Global Information Assurance Certification Paper

Part 1: Analyze an Unknown Binary

Overview of Investigation

John Price has been suspended from his place of employment because an audit revealed that company resources might be in use for illegal transfer of copyrighted material. Mr. Price wiped the hard disk of his company PC before an investigation could be undertaken, but a single floppy was seized. Mr. Price disclaims ownership of the floppy, but a forensic analysis of the floppy makes this claim unlikely. Of particular interest is a single binary file on the floppy, named "prog". **Forensics analysis reveals that this program is a Linux executable and is a version of the data hiding tool "bmap" (see Section Program Identification for background)**. The program allows storage of arbitrary data in the slack space of a file.

An investigation of the floppy is detailed below. The following equipment and software was used in the analysis of the floppy:

Primary forensics machine:

T40p Thinkpad with (1) 60GB 7200 rpm disk and 2GB RAM running Windows XP. Forensics software used: Accessdata's Forensics Toolkit ("FTK") v1.43a.

Secondary forensics machine, used to execute the unknown binary in a controlled environment:

A31p Thinkpad with (1) 60GB 7200 rpm disk and 512MB RAM running Redhat Linux 9 with a 2.4.20-8 kernel. GCC version is 3.2.2. Filesystem is ext3.

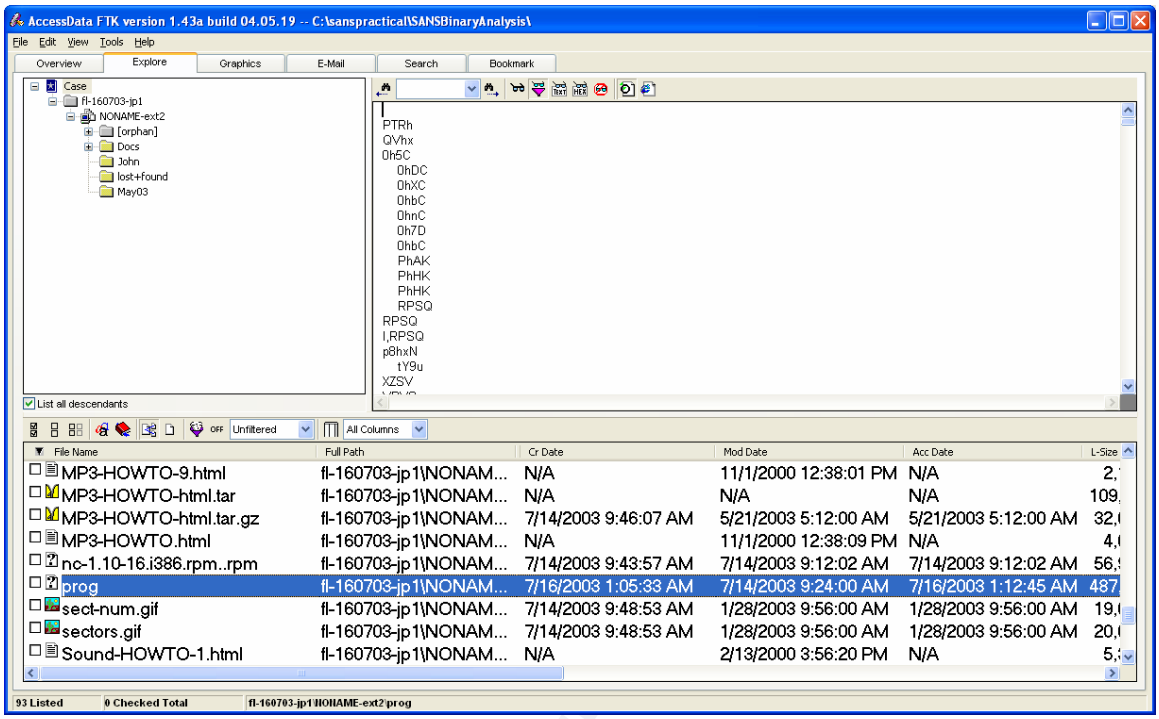
Binary Details and Program Description

The floppy image was loaded into FTK by creating a new case. Details of the FTK imaging process, options available when creating a new case, and options that control FTK's initial preprocessing for evidentiary items are covered in detail in Section "Media Analysis of the System" in Part (2) of this practical. All of the default options were used when opening the case for analysis of the unknown binary. The case name chosen was "SANSBinaryAnalysis".

FTK provided the following information on the binary "prog". This information was obtained from the Explore view in FTK after clicking on "prog". A screenshot illustrates the information.

Inode changed (file "created") 7/16/2003 1:05:33am
Modified 7/14/2003 9:24:00am
Accessed 7/16/2003 1:12:45am
User: 502 Group: 502

Screenshot of “prog” info in FTK:

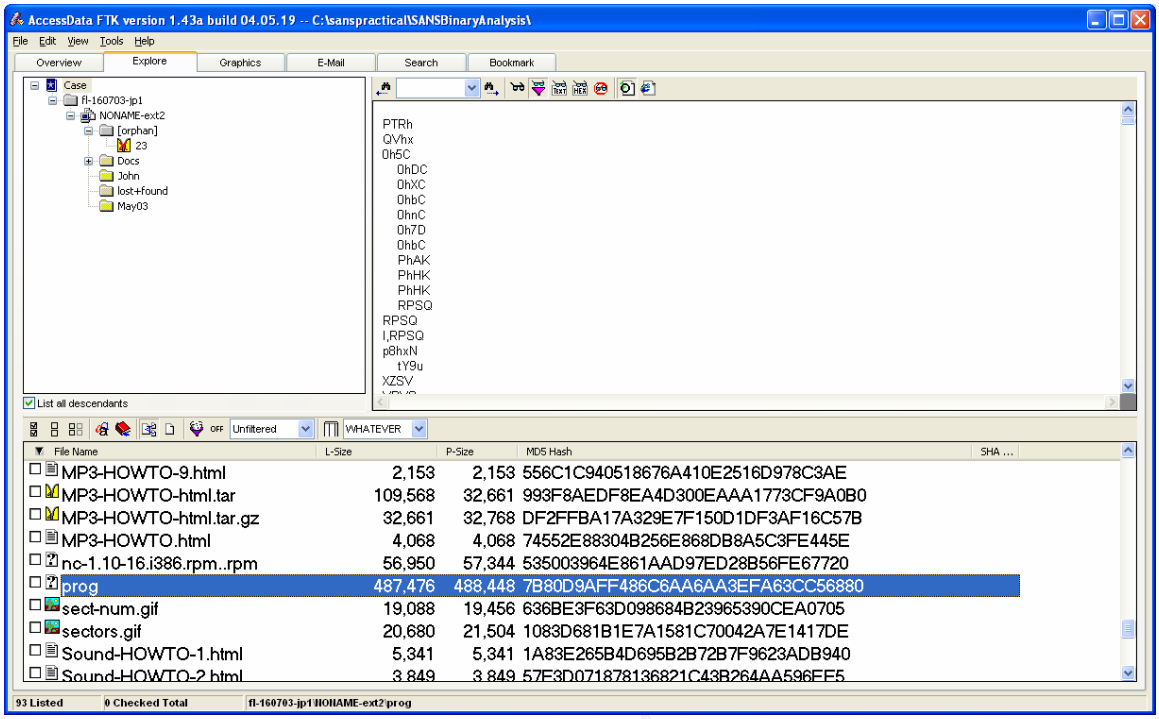


These dates suggest that the file was created (most likely on a different host) on 7/14/2003, then subsequently copied to the floppy on 7/16/2003, then accessed approximately 7 minutes later on 7/16/2003. Of course these times are not completely reliable, since a user can manipulate the system time and/or use the ‘touch’ command to modify them. The modification date prior to the inode changed date implies a transfer from another filesystem to the floppy, barring a user tampering with the MAC times via manipulation of the system clock. Scrolling to the right in the FTK view of “prog” shows file size and MD5 hash info:

File size: 487,476 (logical) / 488,448 (physical)

MD5 hash of “prog”: 7B80D9AFF486C6AA6AA3EFA63CC56880

Screenshot from FTK illustrating MD5 hash and file sizes for “prog”:



In order to fully investigate 'prog', it was exported from FTK and installed on the secondary forensics investigation machine, running Redhat Linux. To export a file from FTK, simply right click on the file in the Explorer view.

On the Redhat Linux box, the command:

```
./prog --help
```

yields the help screen for "prog", shown below:

```
prog:1.0.20 (07/15/03) newt
Usage: prog [OPTION]... [<target-filename>]
use block-list knowledge to perform special operations on
files

--doc VALUE
  where VALUE is one of:
  version  display version and exit
  help  display options and exit
  man  generate man page and exit
  sgml  generate SGML invocation info
--mode VALUE
  where VALUE is one of:
  m  list sector numbers
  c  extract a copy from the raw device
  s  display data
```

```
  p  place data
  w  wipe
  chk  test (returns 0 if exist)
  sb  print number of bytes available
  wipe  wipe the file from the raw device
  frag  display fragmentation information for the file
  checkfrag  test for fragmentation (returns 0 if file is
fragmented)
--outfile <filename> write output to ...
--label   useless bogus option
--name    useless bogus option
--verbose be verbose
--log-thresh <none | fatal | error | info | branch |
progress | entryexit> logging threshold ...
--target <filename> operate on ...
```

"prog" is program that allows performs special operations on files using low-level block list information. Essentially, "prog" is useful for storing and retrieving data from the slack space of a file. In non-technical terms, this means that "prog" allows data to be hidden in existing files. Uses might include hiding passwords or lists of contacts.

"prog" operations include introducing data into the slack space of a file, retrieving the data stored in the slack space by the program, wiping the data stored in the slack space, checking to see if a file is fragmented (that is, if its blocks are not contiguously allocated), and listing sector numbers allocated to a file. The program is self-documenting and can generate its own man page and SGML documentation, which were analyzed to further understand the uses of the program. The application is evidently version 1.0.20, dated 7/15/03. The application was last accessed (and thus potentially executed, although simply viewing the contents of the file or executing the 'touch' command on the file would have the same effect on the access timestamp) on 7/16/2003 at 1:12:45am.

All of the operations supported by the application were tested to verify their functionality, with an eye on verifying that the documented uses of the program coincide with the actual operations performed by the program. The "wipe" operation is presumably for securely deleting a file from disk; this operation failed with multiple "write error" messages on the test machine and could not be evaluated further. The "—label", "—name", and "—target" options appear to be specific to a particular execution environment **(this was gleamed from source code for bmap, once it was determined that "prog" is actually bmap—see Section Program Identification for more details)** and were not usable on the test machine. The three most significant options allow data to be inserted into an arbitrary file's slack space, testing for data stored in the slack space of a file, and for the data stored in the slack space to be retrieved. These operations are illustrated below, where a short text string ("forensics is fun") is inserted into "redrose.JPG", a ~500K JPEG image of a rose, the slack space is checked, and the string is finally retrieved.

Storage of a string in slack space:

```
[root@localhost root]# ./prog -s redrose.JPG
stuffing block 558131
file size was: 503344
slack size: 464
block size: 4096
forensics is fun          ← this string typed in by user
```

Checking slack space:

```
[root@localhost root]# ./prog chk --mode chk redrose.JPG
redrose.JPG has slack
```

Retrieval of a string in slack space:

```
[root@localhost root]# ./prog -s redrose.JPG
getting from block 558131
file size was: 503344
slack size: 464
block size: 4096
forensics is fun
```

Further analysis of the application was performed in Section "Program Identification". In particular, strace (system call trace) was used to verify that the application doesn't tamper with system files or perform other "nasty" operations.

Forensic Details

Output of analysis of "prog" using the Unix "strings" command appears in Appendix A. The strings output contains a number of "/dev/XXXX" entries, which are hard-coded in the bmap library used by 'prog' (this was discovered during investigation of the bmap source code, discussed further in the next section). These device entries are omitted in the listing in Appendix A, because they fill approximately 100 pages. Aside from this omission, the strings output is identical to execution of the following command against the executable (which sorts the strings output and removes duplicate lines):

```
# strings prog | sort | uniq
```

The strings analysis is of limited forensic value except to establish that "prog" and "bmap" are similar. More discussion on this issue appears in the next section, Program Identification. One name and email address are revealed in the strings output and not included in the program's help screen: Keld Simonsen → keld@dkuug.dk. A Google search for "Keld Simonsen" reveals that Keld is working on international standardization for the C programming language [6]. This means that the inclusion of his name in the

binary is likely a result of linking against the standard C library. The following test supports this suspicion:

```
# strings /usr/lib/libc.a | grep –i simonsen
```

on the secondary forensics machine running Linux yields the following:

```
Keld Simonsen
C/o Keld Simonsen, Skt. Jorgens Alle 8, DK-1615 KobenHavn V
```

There is little reason to suspect any further connection between Keld Simonsen and the binary.

System call traces in the following section, Program Identification, do not reveal that any system files (other than the target device, e.g., /dev/hda1) are used by 'prog'. No changes to the /dev/XXXX entries are apparent after execution of "prog". Note that system call traces are included in the next section rather than in this section for continuity, since a close scrutiny of the system call traces of "prog" and "bmap" is used to establish that the programs are functionally equivalent.

Forensics "footprints" are discussed in detail in Sections Program Identification and Case Information. These details are not duplicated here, but briefly, "prog"/bmap will store and retrieve the data stored in an individual file's slack space, so one possible method for determining if "prog"/bmap is in use on a system is to examine individual files using "prog"/bmap, to see if stored data is present. The "-s" option in "prog" can be used for this.

Program Identification

A Google search on "use block-list knowledge to perform" revealed that the program is likely a version of "bmap" [1]. It is discussed briefly on several web pages, including an article on Linux data hiding and recovery [2]. A link to a bmap download site (ftp://ftp.scyld.com/pub/forensic_computing/bmap/) exists on [3] but the link is broken. An anonymous ftp attempt to ftp.scyld.com reveals that the "forensic_computing" directory no longer exists. An older version of the bmap software (v. 1.0.17) is available at [4]. This location was found using Google with keywords "bmap" and "forensics". A subsequent search on Google for "bmap-1.0.20.tar.gz" (using the same syntax for the filename as in the older 1.0.17 version [4]) yielded a site where the source tarball could be downloaded [5].

The tarball was expanded using the following command:

```
tar –xzvf bmap-1.0.20.tar.gz
```

The following files are contained in the tarball:

```
bmap-1.0.20/COPYING
bmap-1.0.20/LICENSE
bmap-1.0.20/Makefile
bmap-1.0.20/README
bmap-1.0.20/bclump.c
bmap-1.0.20/bmap.c
bmap-1.0.20/bmap.sgml.m4
bmap-1.0.20/bmap.spec
bmap-1.0.20/dev_builder.c
bmap-1.0.20/include/bmap.h
bmap-1.0.20/include/slacker.h
bmap-1.0.20/index.html
bmap-1.0.20/libbmap.c
bmap-1.0.20/man/man2/libbmap.2
bmap-1.0.20/mft/COPYING
bmap-1.0.20/mft/Makefile
bmap-1.0.20/mft/README
bmap-1.0.20/mft/helper.c
bmap-1.0.20/mft/include/helper.h
bmap-1.0.20/mft/include/info.h
bmap-1.0.20/mft/include/log.h
bmap-1.0.20/mft/include/mft.h
bmap-1.0.20/mft/include/option.h
bmap-1.0.20/mft/log.c
bmap-1.0.20/mft/option.c
bmap-1.0.20/slacker-modules.c
bmap-1.0.20/slacker.c
```

The author and maintainer of bmap is apparently Daniel Ridge, of Scyld Computing Corporation. This is documented in the README and in the source files for "bmap".

Issuing the file command on "prog" reveals that it is a statically linked and stripped executable. An initial compile of "bmap" (by simply issuing "make") resulted in a dynamically linked version, with a size significantly smaller than "prog". **The Makefile was then modified to create a statically linked "bmap" by changing the CFLAGS in the Makefile to include "-static".** The resulting executable was then stripped with the command "strip bmap". File sizes of "prog" and "bmap" still did not match.

Upon execution of the compiled bmap, it's obvious that the applications are not identical, at least cosmetically. While they both carry the 1.0.20 version number, the command line options of 'prog' are significantly shorter (e.g., "-s" or "—mode s" for "prog" compared to "-slack" or "—mode slack" for bmap). To see this, compare the help screen for "prog" in Section Binary Details and the following help screen for the compiled "bmap":

```
bmap:1.0.20 (05/12/04) newt@scyld.com
Usage: bmap [OPTION]... [<target-filename>]
use block-list knowledge to perform special operations on
files

--doc VALUE
  where VALUE is one of:
  version  display version and exit
  help  display options and exit
  man  generate man page and exit
  sgml  generate SGML invocation info
--mode VALUE
  where VALUE is one of:
  map  list sector numbers
  carve  extract a copy from the raw device
  slack  display data in slack space
  putslack  place data into slack
  wipeslack  wipe slack
  checkslack  test for slack (returns 0 if file has slack)
  slackbytes  print number of slack bytes available
  wipe  wipe the file from the raw device
  frag  display fragmentation information for the file
  checkfrag  test for fragmentation (returns 0 if file is
fragmented)
--outfile <filename> write output to ...
--label   useless bogus option
--name    useless bogus option
--verbose be verbose
--log-thresh <none | fatal | error | info | branch |
progress | entryexit> logging threshold ...
--target <filename> operate on ...
```

One possibility is that a user of "bmap" customized the options to reduce typing effort. Even if the application source codes were identical, the file sizes of the executables might not match, due to use of different versions of gcc and the standard C libraries during compilation. MD5 sums were not compared for "prog" and the compiled version of "bmap" because it is known that the files are not the same.

Strings analysis of "bmap" (see Appendix B for the sorted, unique strings obtained) yields results very similar to that for "prog" (strings analysis for "prog" appears in Appendix A). In fact, the most significant differences relate to the help screen (accessible using the "-h" option for either program), since the text on the screens is different.

A functional test combined with use of strace (which traces the systems calls executed by an application) reveal that 'prog' and 'bmap' are essentially the same, however. All of the useful options were evaluated, producing identical results on a set of test files.

Representative system calls traces for 'prog' and 'bmap', with the command lines used to generate them, follow.

Storage of string "Hello" in slack space of a ~500K file "FILE" using 'prog':

Command line:

```
strace –o /tmp/STRACE_PROG_STORE ./prog –p FILE
```

(-o option for strace specifies an output file for the trace; the command line option –p for prog is equivalent to –mode putslack for bmap)

Contents of /tmp/STRACE_PROG_STORE:

```
execve("./prog", ["./prog", "-p", "FILE"], [/* 36 vars */])

```

The bold write statements above illustrate what was displayed on the screen during execution of the application. The bold read statement is a read from standard input of the

data to be stored in slack space. The underlined write statement is writing the string into the file's slack space (following a seek, 2 lines previous).

Storage of string "Hello" in slack space of a ~500K file "FILE" using 'bmap':

Command line:

```
strace –o /tmp/STRACE_BMAP_STORE ./bmap –-mode putslack FILE
```

Contents of /tmp/STRACE_BMAP_STORE:

```
execve("./bmap", ["./bmap", "--mode", "putslack",
"../FILE"], [/* 36 vars */]) = 0
uname({sys="Linux", node="localhost.localdomain", ...}) = 0
fcntl64(0, F_GETFD)                     = 0

```

With one exception, differences in the system call traces above for storage of data in slack space are attributable to different compilation environments—they are functionally equivalent. The difference is that a different target block number is seen in the first bold write statement. This is because a copy of the original file "FILE" was used for the "bmap" execution (e.g., a backup of FILE was made before execution of "prog" and after execution of "prog", this file was renamed to "FILE" before execution of "bmap"). No evidence of forensically significant events such as modification of system files by one version but not the other are evident.

Retrieval of string “Hello” from slack space of the file “FILE” using ‘prog’

Command line:

```
strace –o /tmp/STRACE_PROG_SHOW ./prog –s FILE
```

(-s causes prog to show the contents of slack space for a file and is equivalent to –mode slack for bmap)

Contents of /tmp/STRACE_PROG_SHOW:

```
execve("./prog", ["./prog", "-s", "FILE"], [/* 25 vars */])
= 0

```

The bold write statements above illustrate what was displayed on the screen during execution of the application. The underlined read statement is a read against /dev/hda1 (following a seek 2 lines previous) that retrieves the hidden data from the file slack.

Retrieval of string “Hello” from slack space of the file “FILE” using ‘bmap’

Command line:

```
strace –o /tmp/STRACE_BMAP_SHOW ./bmap –-mode slack FILE
```

Contents of /tmp/STRACE_BMAP_SHOW:

```
execve("./prog", ["./prog", "-s", "FILE"], [/* 25 vars */])

```

Differences in the system call traces above for retrieval of data from slack space are attributable to different compilation environments—they are functionally equivalent. In particular, no evidence of forensically significant events such as modification of system files by one version but not the other are evident.

Note that in all of the system call traces, only file system operations are performed. That is, all handles correspond to open files. There is no evidence that the program performs any network operations, because there are no I/O operations performed on handles other

than those corresponding to open files. This rules out TCP connections. Further, there are no system calls that could be attributable to UDP or IP packet transmission.

Another interesting fact is that "prog" can only be run as superuser, since it directly accesses the hard drive (refer to the open of "/dev/hda1", for example). This has some legal implications in case the suspect wasn't supposed to have root access on the machines he had access to.

One critically important point is that use of "prog" (or "bmap") does not change file timestamps. To see this, consider the following three command sets, each of which displays the system date, executes stat to show the MAC times for the file "FILE", executes a "prog" operation against "FILE", and finally, executes stat again to view the MAC times.

"prog" in 'chk' mode:

```
[root@localhost root]# date ; stat FILE ; ./prog --mode chk FILE ; stat
FILE

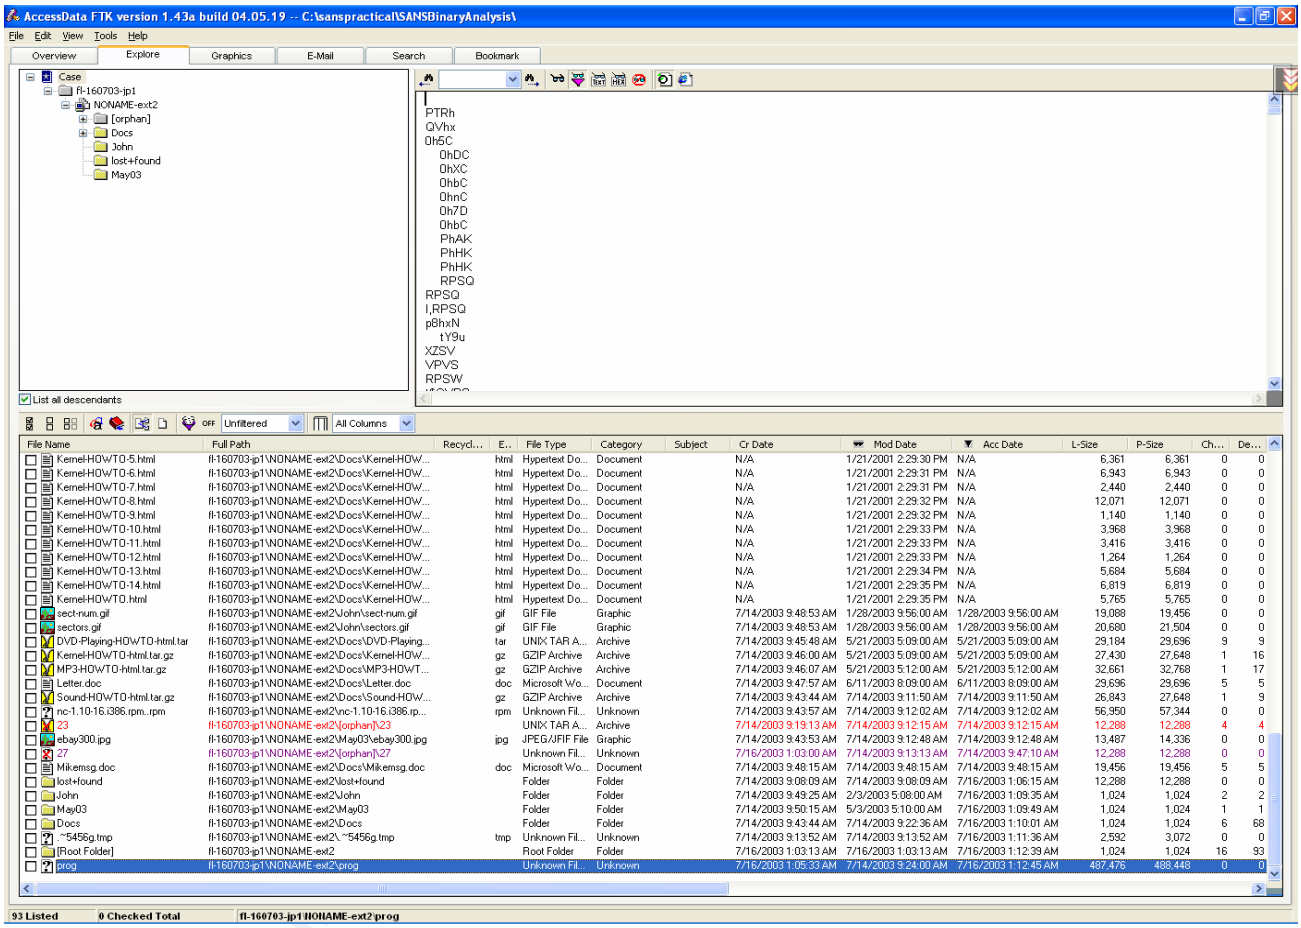
Thus file access times cannot be used to determine whether "prog" (or "bmap") have been used on a file.

Legal Implications

It is not possible to establish that this version of the program was actually executed given only the evidence on the floppy. The access time of 'prog' is the latest access time on the entire floppy, as illustrated in the FTK screenshot below (where all files present on the floppy, including deleted files, are sorted by access time):



The user could simply have issued the 'touch' command on the executable. However, it seems likely that the suspect executed "prog". Unfortunately, as outlined in the last section, "prog"/"bmap" do not change file access times for target files. In order to determine if data has been stored in slack space on the floppy, the contents of the floppy were evaluated as follows:

An image of the floppy was mounted read-only using the loopback device on the secondary forensics box, running Linux:

```
# mount –r /mnt/usbkey/fl-160703-jp1.dd /mnt/loop –o loop
```

"prog" was then run against each file on the floppy, with the output redirected to a file. For example:

```
# ./prog –p file /mnt/loop/Docs/Mikemsg.doc > FILE
```

The contents of FILE was then evaluated either visually and with the "file" command. One significant hit was found, on the file "Docs/Sound-HOWTO-html.tar.gz", which generated an 805 byte output from "prog". Executing "file" on this output revealed a gzip-compresssed file:

```
# file FILE

FILE: gzip compressed data, was "downloads" from Unix
```

FILE was then renamed to "downloads.gz" and uncompressed using gzip –d:

```
# mv FILE downloads.gz
# gzip –d downloads.gz
```

The file "downloads" contains ASCII text:

```
Ripped MP3s - latest releases:

www.fileshares.org/
www.convenience-city.net/main/pub/index.htm
emmpeethrees.com/hidden/index.htm
ripped.net/down/secret.htm

***NOT FOR DISTRIBUTION***
```

This provides evidence that the suspect might have been using these sites to download ripped MP3s. If he did, then he violated Copyright Act of 1976 as well as the newer Digital Millennium Copyright Act (DMCA). In particular, even if the suspect owned the original sources for the MP3s, he is not entitled to distribute them freely. The presence of a list of MP3 sites also supports the theory that the suspect might have used "prog" (although another individual could have used "bmap" on the floppy, since they are functionally equivalent). The use of prog/bmap to simply hide ASCII text, however, would not specifically violate any internal policies of my organization—we have no restrictions on the use of data hiding software and there is no evidence of copyrighted material on the floppy. Beyond that, simply storing non-copyrighted ASCII text would not violate any other U.S. laws, either. **If additional evidence can be obtained (e.g., network traces) that illustrate that MP3s were downloaded from these sites, then a much stronger case could be made.**

Note: Given a larger number of files to check, it would make sense to develop a short script to automate the use of "prog"/"bmap" and evaluation of the output for each file. This could be written easily in Perl. Given the small number of files, manual evaluation was sufficient.

Other Evidence

A Microsoft Word document with filename "/Docs/Mikemsg.doc" and MD5 hash 82D58D80782A3C017738D00D3A33E2B9 contains the following message:

Hey Mike,

I received the latest batch of files last night and I'm ready to rock-n-roll (ha-ha).

I have some advance orders for the next run. Call me soon.

JP

Analysis of the metadata for the Word document in FTK reveals that the document was created by John Price and its original location was "C:\Documents and Settings\Administrator\Desktop\Mikemsg.doc". This information can be obtained either by viewing the Word file in "Raw Text Format" in FTK or by examining the associated OLE stream containing this info, which FTK provides as a separate item. The pun on "rock-n-roll" suggests that digital media is being transferred or sold.

A number of documentation files exist on the floppy, explaining how to configure playing of MP3s and DVDs under Linux.

An RPM for netcat 1.10-16 is present on the floppy. netcat can be used for quickly establishing client/server connections for file transfers, remote command execution, etc. It could potentially have been used for transfer of files to other machines.

Case Information

There is evidence that indicates company resources were being used by John Price to distribute copyrighted material, but additional evidence would be useful. A program "prog" was installed on the evidence floppy that allows storage of arbitrary data in the slack space of files. In non-technical terms, the program allows arbitrary data to be hidden in existing files. This program, "prog", (or it's functionally equivalent relative, "bmap") was used to hide a list of MP3 download sites on the floppy. The available evidence includes this list of MP3 download sites, a letter to "Mike" implying that a new batch of material is available and that some charge is being made for the files. Further,

the presence of a netcat package, which allows network connections to be established between machines and files to be transferred, is suspicious (unless use of netcat is within the scope of John Price's duties). If network traces (or a backup of the wiped hard drive) were available, a much more damning case might be assembled.

More information on testing for use of "prog"/"bmap"

Alone, the "prog"/"bmap" application has limited usefulness, since the size of the slack space for a single file is limited. It was sufficient in this case for the user to hide a list of MP3 download sites. Another application included in the bmap distribution, called "slacker", allows the aggregate slack space of a directory to be used for storage and retrieval of large amounts of data. Slacker can recursively walk a directory tree, using the available slack space of each file for storage of data. For example, the command:

```
# slacker –mode fill /mnt/floppy < index.html
```

will store the contents of the file "index.html" in the aggregate slack space of all the files on a mounted floppy drive. The command

```
# slacker –mode our /mnt/floppy > retrieved_index.html
```

will retrieve the stored data and write it to a file "retrieved_index.html".

bmap will retrieve the data stored in an individual file's slack space, so one possible method for determining if bmap/slacker are in use on a machine would be to examine individual files using bmap, to see if stored data is present. This is the method used in the present investigation. A much easier method may be available using slacker, however. Consider the following command:

```
[root@localhost bmap-1.0.20]# ./slacker --mode capacity
/mnt/usbkey/recipes
```

This command evaluates the aggregate slack storage capacity of the directory "/mnt/usbkey/recipes", which is a collection of recipes stored on a USB thumbdrive:

```
examining /mnt/usbkey/recipes/almondapricotbiscotti.htm
slack bytes: 4
examining /mnt/usbkey/recipes/coldcarrotsoup.htm
slack bytes: 287
examining /mnt/usbkey/recipes/corbybiscotti.htm
slack bytes: 472
examining /mnt/usbkey/recipes/datebars.htm
slack bytes: 415
examining /mnt/usbkey/recipes/escarolesoup.htm
slack bytes: 124
examining /mnt/usbkey/recipes/mushroomsorzo.htm
slack bytes: 55
```

```
examining /mnt/usbkey/recipes/orzorisotto.htm
slack bytes: 248
examining /mnt/usbkey/recipes/salad.htm
slack bytes: 430
examining /mnt/usbkey/recipes/salad_files
examining /mnt/usbkey/recipes/salad_files/ad1.js
slack bytes: 7
examining /mnt/usbkey/recipes/orzorisotto_files
examining /mnt/usbkey/recipes/orzorisotto_files/ad1.js
slack bytes: 7
examining /mnt/usbkey/recipes/mushroomsorzo_files
examining /mnt/usbkey/recipes/mushroomsorzo_files/ad1.js
slack bytes: 7
examining /mnt/usbkey/recipes/escarolesoup_files
examining /mnt/usbkey/recipes/escarolesoup_files/ad1.js
slack bytes: 7
examining /mnt/usbkey/recipes/datebars_files
examining /mnt/usbkey/recipes/datebars_files/ad1.js
slack bytes: 7
examining /mnt/usbkey/recipes/corbybiscotti_files
examining /mnt/usbkey/recipes/corbybiscotti_files/res0.gif
slack bytes: 448
examining /mnt/usbkey/recipes/corbybiscotti_files/res1.gif
slack bytes: 344
examining /mnt/usbkey/recipes/corbybiscotti_files/res2.gif
slack bytes: 510
examining /mnt/usbkey/recipes/corbybiscotti_files/res3.gif
slack bytes: 308
examining /mnt/usbkey/recipes/coldcarrotsoup_files
examining /mnt/usbkey/recipes/coldcarrotsoup_files/ad1.js
slack bytes: 7
examining /mnt/usbkey/recipes/almondapricotbiscotti_files
examining
mnt/usbkey/recipes/almondapricotbiscotti_files/ad1.js
slack bytes: 7

unformatted capacity: 3694
formatted capacity: 3553
unformatted free: 3641
formatted free: 3553
```

The aggregate storage available is 3553 bytes, all of which are currently available. This seems to indicate that bmap/slacker (or a similar mechanism) have not been used on the system.

The following command was then used to store the contents of a 913 byte HTML file "index.html" in the available slack space:

```
[root@localhost bmap-1.0.20]#./slacker --mode fill
/mnt/usbkey/recipes < index.html
```

A subsequent "capacity" test reveals that some of the capacity has been used (the output is abbreviated to show only the summary information):

```
[root@localhost bmap-1.0.20]# ./slacker --mode capacity
/mnt/usbkey/recipes

<<some output not shown>>
unformatted capacity: 3694
formatted capacity: 3553
unformatted free: 2467
formatted free: 2403
```

This provides an interesting test for a systems administrator to apply to determine if bmap/slacker has been used, since slacker can be applied to entire directory trees. This hypothesis needs further validation, since it is possible that some other utilities might interfere with the use of slacker in this manner. Due to time constraints, this validation was not undertaken.

Interview Questions

1. Who is "Mike"? What is the nature of the batch of files you mention in your message to Mike?

2. Have you ever used data hiding software? Have you ever heard of "bmap"?

3. Have you ever used "ncat"?

4. Why did you wipe the hard drive of your desktop?

5. Why were you interested in MP3 and DVD playing under Linux?

6. Have you ever downloaded files from www.fileshares.org or www.ripped.net?

Part 2 (Option 1): Perform Forensic Analysis on a System

Synopsis of Case Facts

My department maintains one "open" laboratory for teaching computer literacy and providing general access to Windows machines. Students wishing to use the lab must obtain a username and password, but the machines are not dedicated to particular users and are not backed up. A policy document is distributed to students using the lab. This document is reproduced below, with portions that would identify the particular department deleted, as per GIAC practical examination guidelines:

<<DELETED>>

<<DELETED>>

Literacy Laboratory

Computer Account Guidelines

Your account is intended for use related to the <<DELETED>> Computer Literacy Course. Failure to adhere to the following guidelines may result in denial of service or deactivation of your account.

- using any other user's account
- allowing any other user to use your account
- using this account for any work not related to this course
- unauthorized use of equipment or facilities
- malicious or destructive use of equipment
- unauthorized copying of system or application software
- attempting to circumvent system security
- any actions that interfere with the usage of the systems by others
- This account may not be used for playing games or interactive "chatting" over the internet.

This document is not to be taken as the boundaries of the law but as the spirit in which your account is used. Just because something is not listed here, does not necessarily make it acceptable.

Full Name	*«FULLNAME»*
Course	*CS «COURSE»* ***Section*** *«section»*
Your username is	*«UNAME»*
Your password is	*«PASSWD»*

In addition to the policy document, all systems are bannered to indicate that personal information should not be stored on the machines, that information contained therein should not be considered confidential and may be monitored to ensure proper administration of the departmental facilities. This investigation targets a random machine pulled from the literacy lab in order to evaluate adherence to the guidelines in the policy document and our banner. Of particular interest is the installation of unauthorized commercial software, downloading of copyrighted materials such as MP3s, and viewing of pornographic images or videos in the laboratory. Routine computer use, such as software development using authorized tools, creation of Word documents and use of the Web are considered OK.

The system was not under my control before beginning the investigation nor was the system in a known state. I am, however, aware of the general class of applications that should be installed on the machine to support coursework.

The investigation was carried out on the following system:

T40p Thinkpad with (1) 60GB 7200 rpm disk and 2GB RAM running Windows XP, with one external 80GB NTFS-formatted USB drive for additional storage. This machine also dual boots Linux.

Forensics software used: AccessData's Forensics Toolkit ("FTK") v1.43a and WinHex 11.15 Specialist Edition.

Description of System Being Analyzed

A single machine was analyzed to determine compliance with lab policies. The machine is described in detail in the following section.

Hardware

TAG # UNO212-1: Dell Optiplex GX1 with serial number BD2VK, 128MB RAM, 500MHz Pentium III with one CD/DVD-ROM and one internal 3.5" floppy drive, running Windows 2000. This machine was used in the lab primarily for computer literacy training and software development, using C and Java. A variety of C and Java development tools, including NetBeans, Microsoft Visual Studio, and the Java JDK were expected to be installed. Microsoft Office and web browsers such as IE or Mozilla were also expected.

TAG # UNO212-2: 6448.6MB (~6GB) Western Digital IDE hard drive with serial # WM6271130795, model # AC26400-75R7 (installed in machine above, imaged for investigation).

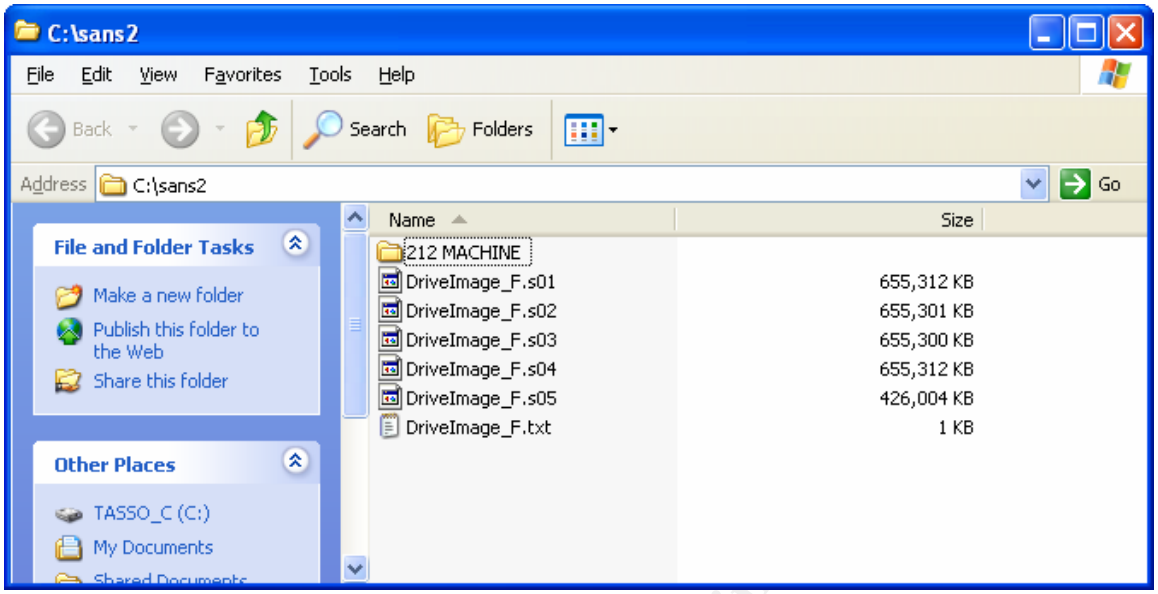
The previous evidentiary items are associated with case identifier SANSPRACTICAL-2.

The system is a 500MHz Pentium III as described above, connected to a switched 100Mb Ethernet. The machine has a connection to the Internet through a 12 X T1 backbone network.

Image Media

One hard drive, with TAG # UNO212-2 was imaged on 1/21/2004 using FTK Imager v2.0. The drive was placed in a USB drive cage before imaging. As an initial precaution, Linux was booted on the analysis machine and the target drive was attached but not mounted, in order to make modification less likely. An md5sum was run against the drive to obtain an MD5 hash. This step was performed to ensure that the FTK imager generated an umodified drive image. Then, using FTK imager, a compressed drive image was obtained, using the target drive as a source and the local drive in the T40p analysis machine as a destination (destination directory C:\SANS2). Output format was compressed SMART format, which requires less space than uncompressed dd format but is completely lossless. The FTK imager supports conversion between dd and SMART format, in case a dd image is needed for use in a different forensics analysis tool.

The MD5 hash for the image is 60D4E476A1554293216479B5D837EEC2, which matches the MD5 hash of the physical drive under Linux. The SMART image fragments have sizes as indicated below:



The size for image fragments was chosen so they could easily be backed up by burning CDs. Note that FTK processes the image fragments as though they were one monolithic image. Although in this investigation an NTFS-formatted drive was used to store the image fragments and so the size of the fragments wasn't significant (since NTFS natively supports very large files), FTK imposes a limit of 2GB for image fragments. This limitation is in place because FAT32 does not support files larger than 2GB.

The FTK image log is shown here:

Information for DriveImage_F

-end-

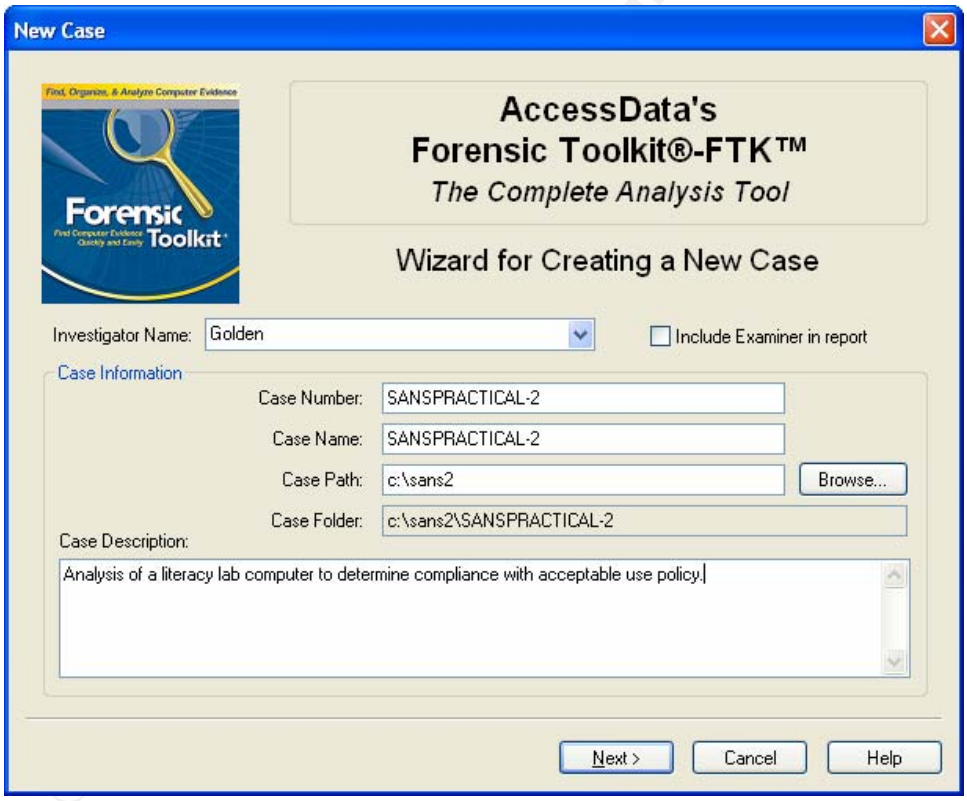
This indicates that the drive image was generated in 5 fragments, with each fragment being roughly 670K in size. The MD5 hash is the hash computed on the generated image.

Media Analysis of the System

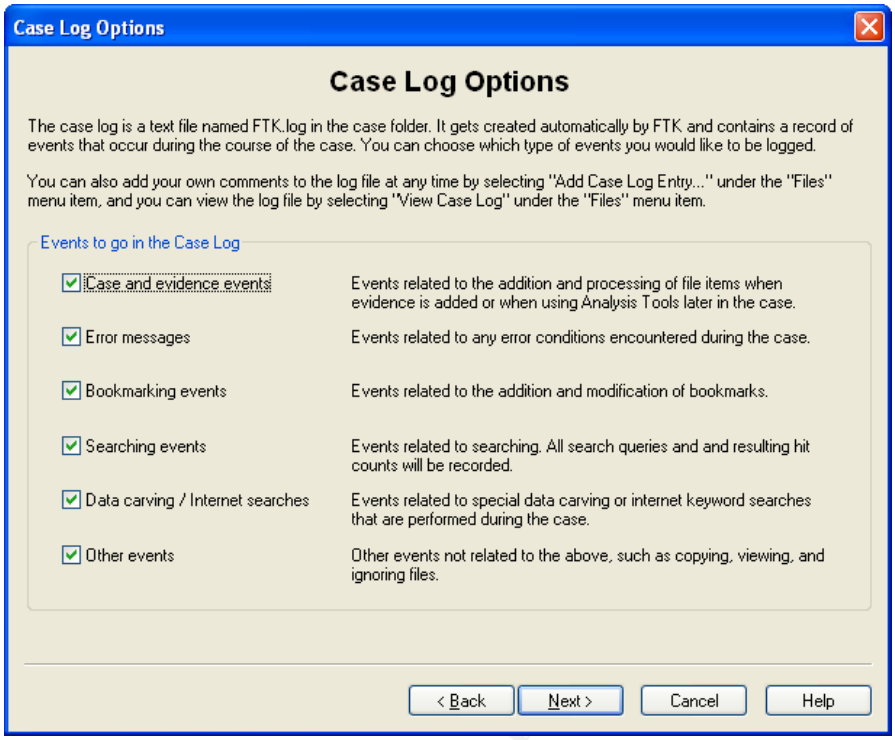
Overview

Media analysis was conducted using AccessData's FTK v1.43a. FTK is a commercial software package that has been extensively validated and operates on drive images in standard formats. It does not modify the image during investigation. FTK incorporates a set of hashes of known files (called the "known file filter", or KFF), both benign and otherwise. This set is based on Hashkeeper, maintained by the National Drug Intelligence Center [1] and on the National Software Reference Library (NSRL), maintained by the National Institute of Standards and Technology (NIST) [2]. The latest hash set available from AccessData, dated 5/19/2004, was used in the investigation.

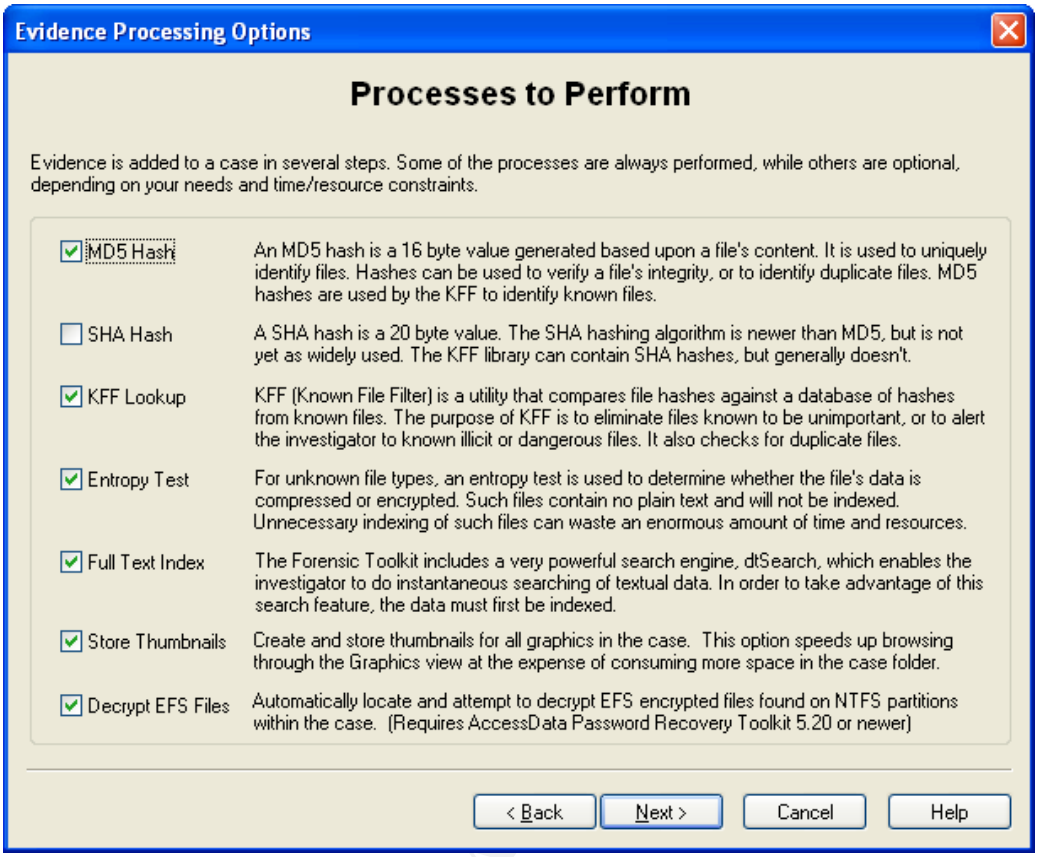
To begin, the new case wizard was used in FTK. The first screen in the wizard collects information about the new case:



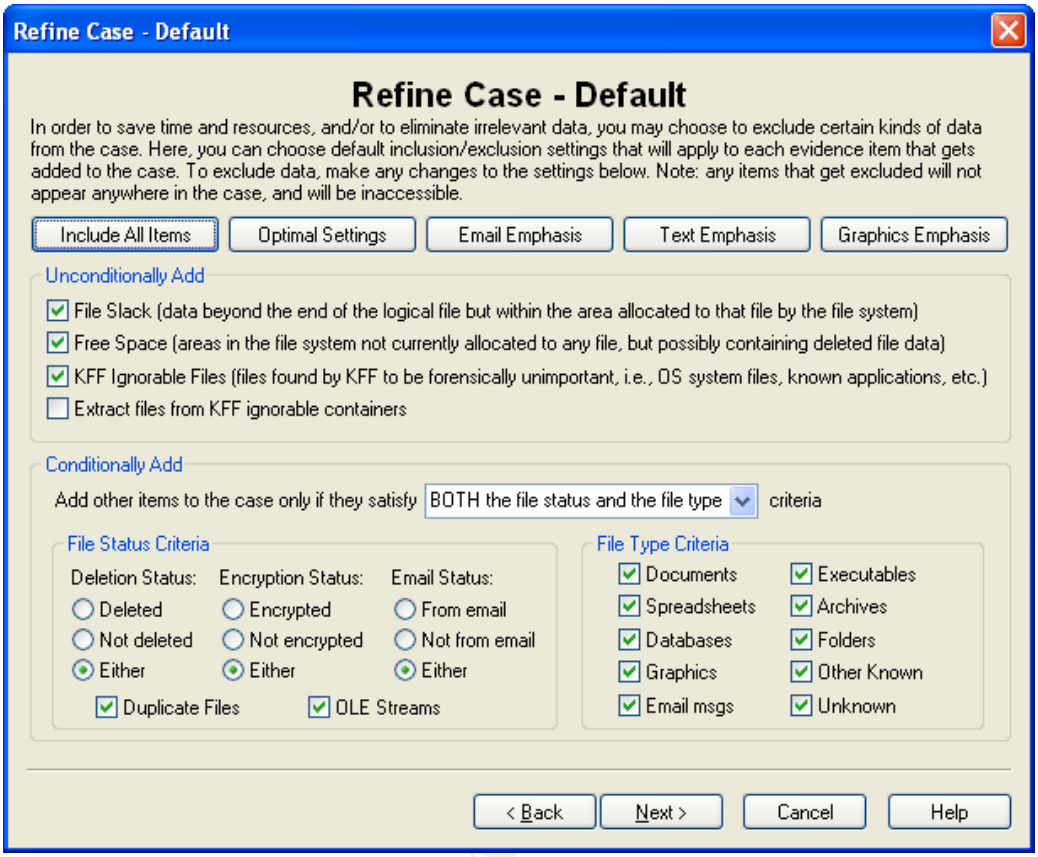
Clicking Next brings up the following screen:



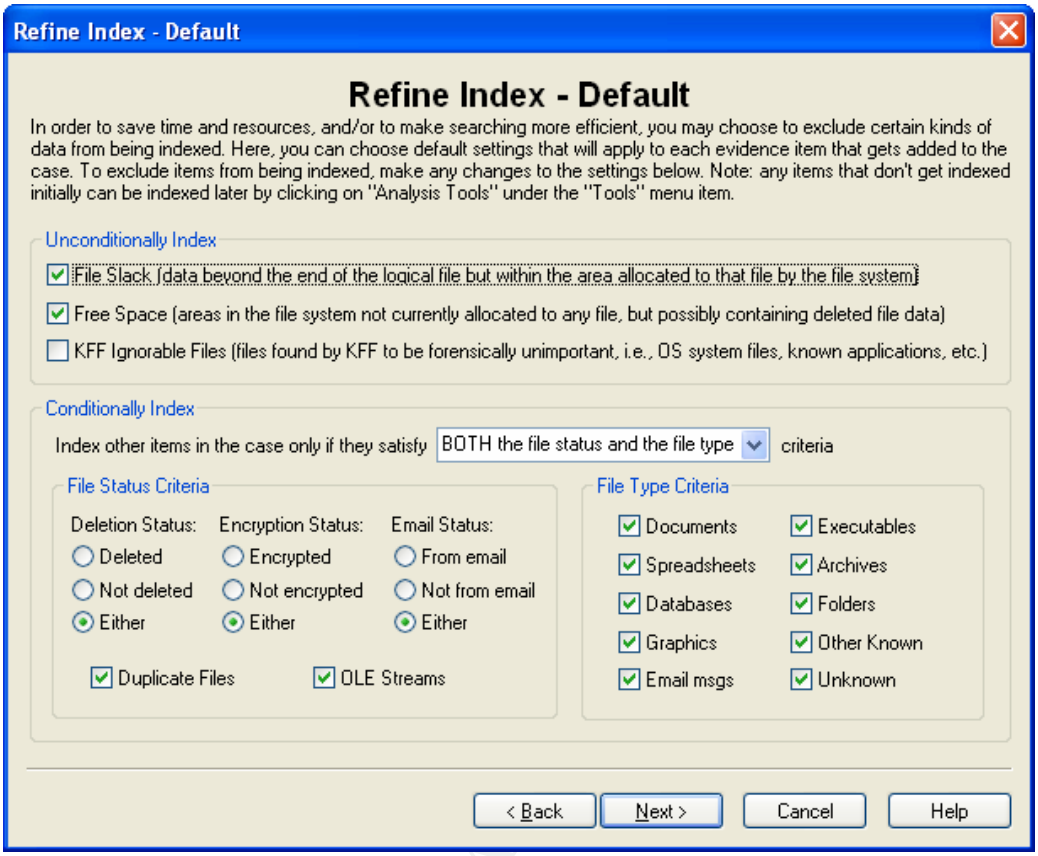
This screen allows an investigator to specify which investigatory events will be included in the FTK case log, which documents steps taken during an investigation. By leaving all of the boxes checked (the default), the FTK case log will be as detailed as possible. Clicking Next brings up the following screen:



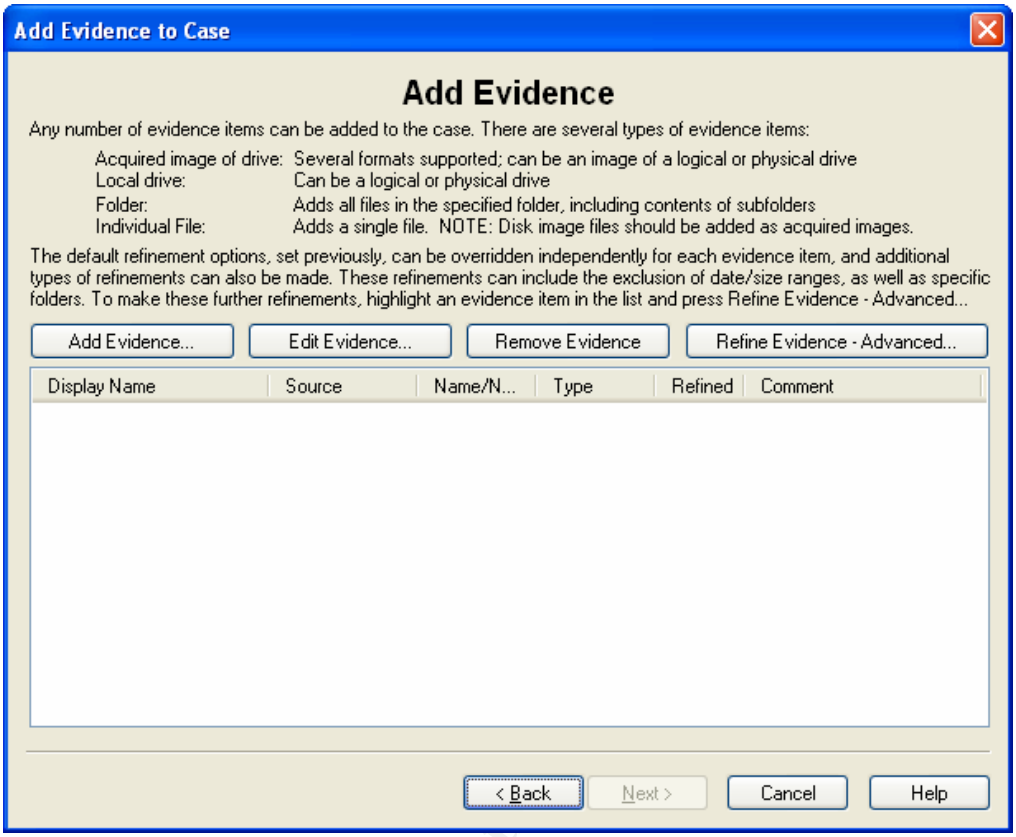
This screen allows the investigator to specify steps FTK should take in initial processing of evidentiary items. The checked options indicate that FTK should take MD5 hashes of all files, check each file against the Known File Filters (KFF) database, which allows exclusion of known files such as operating systems and application files (as well as identification of malware), that entropy tests should be performed to determine if files appear to be compressed or encrypted, that a full text index should be generated (this speeds keyword searching during the investigation), that thumbnails should be generated for all images, and that decryption should be attempted for files on encrypted NTFS partitions. Clicking Next yields:



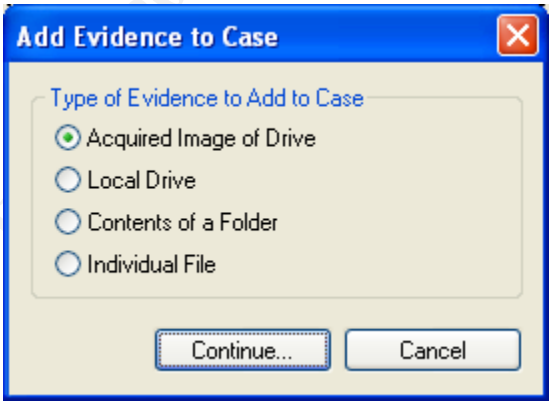
This screen allows an investigator to place emphasis on certain kinds of file evidence, such as inclusion of file slack and free space in the investigative process, whether deleted files should be processed, and which types of documents should be categorized. The default is to include file slack and free space in the investigation, to consider deleted files, and to categorize all known file types. The defaults were accepted. Pressing Next yields the following screen:



This screen is similar to the previous, in that it allows an investigator to target free space and file slack, deleted vs. undeleted files, etc., except that this screen applies to FTK's indexing process only (which builds a database of keyword locations in all evidentiary items). All defaults were accepted. Pressing Next again yields:



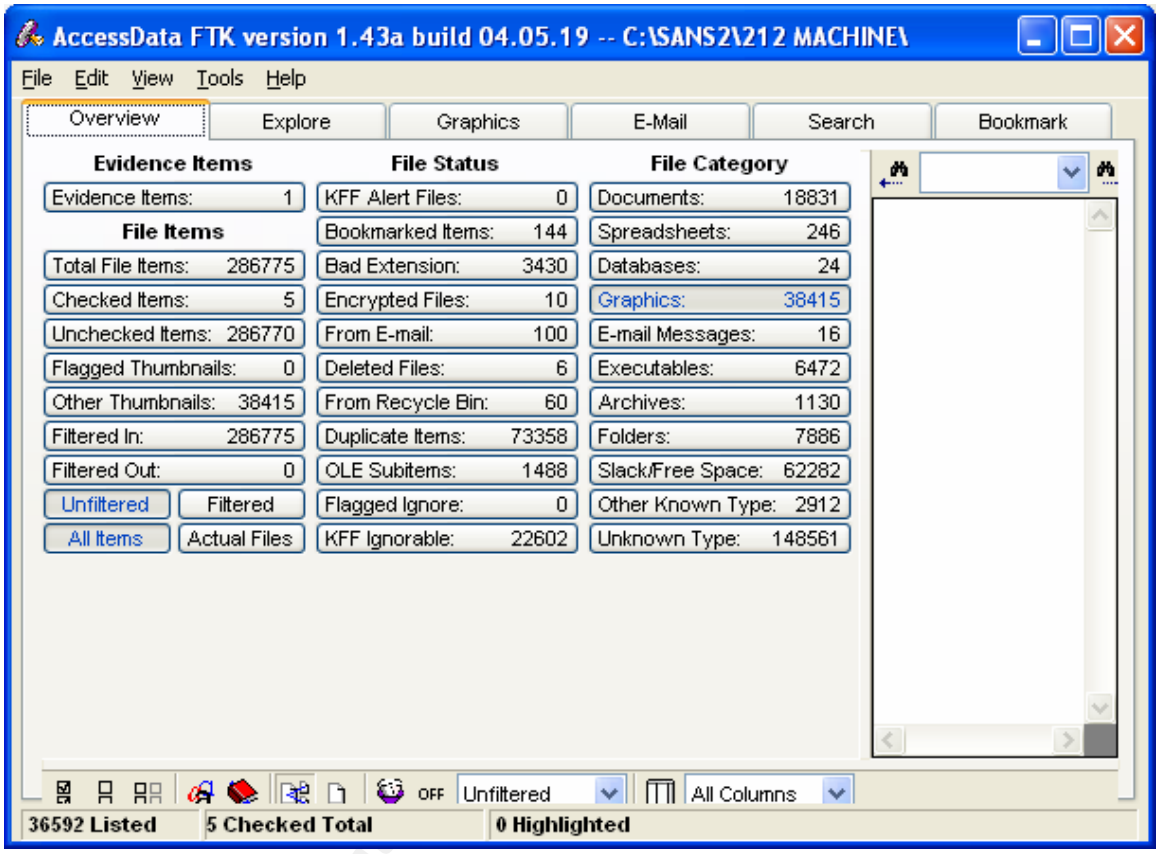
This screen allows the investigator to add (or edit, for an existing case) evidence items. By clicking Add Evidence, the following screen is displayed:



FTK can add either images, the contents of local (attached) drives, folders, or individual files to a case. The default was used, since a SMART format image of the target drive was previously captured using the FTK imager. Pressing Continue yields a file dialog box. "C:\SANS2\driveimage_F.s01" was specified as the image file (this is the first fragment of the SMART format image captured earlier—FTK automatically processes all fragments of the image). FTK then performs indexing operations, which can be very time-consuming for large drives. For the target drive in this case, approximately 2 hours

of indexing was required. After indexing, the case can be opened and the investigation can begin.

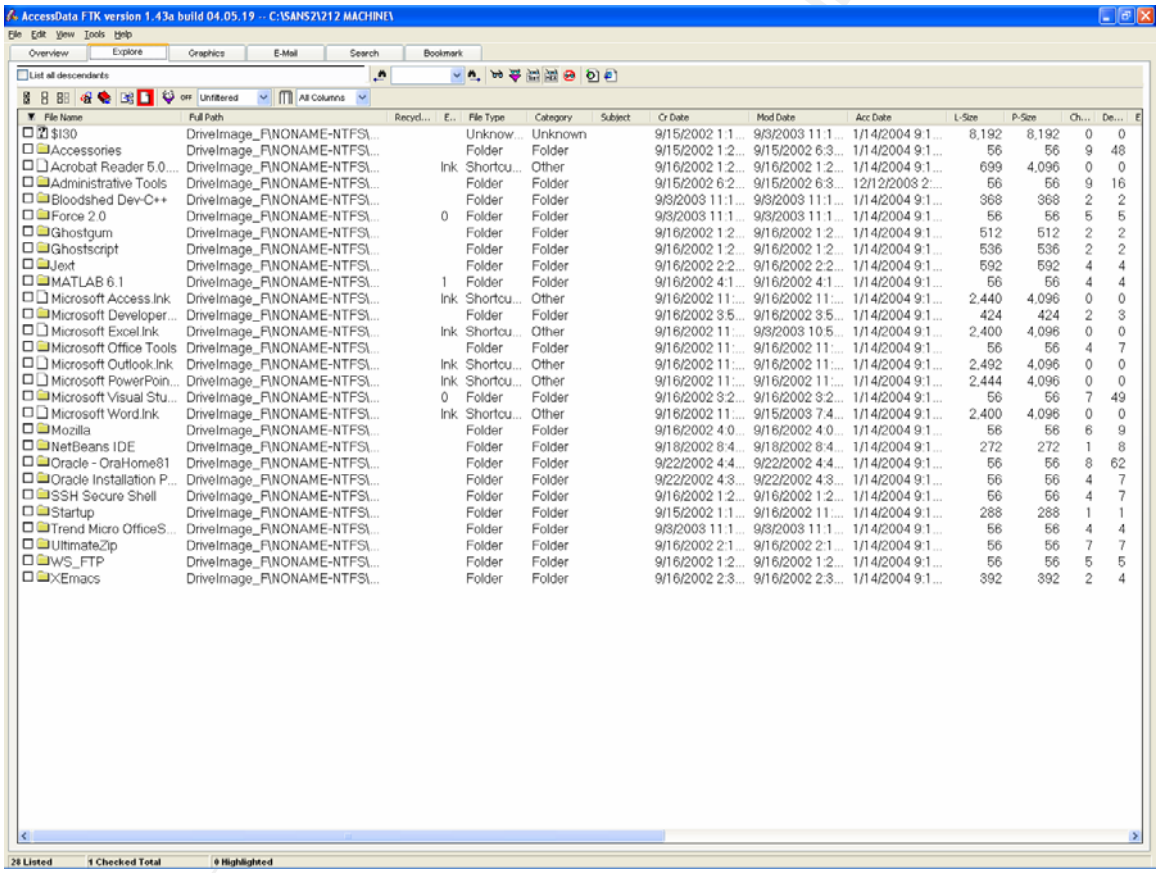
When File→Open Case is used in FTK, the case Overview is the default view. This view is depicted in the screen shot below and shows the total number of files, the number of image files, document files, databases, etc.:



Considering the FTK Overview, a total of 286,775 files were identified. Of these, FTK reports 6 deleted files, 22,602 files marked ignorable being they match hashes for known operating systems and applications files (these matched entries in the KFF database, described earlier), 73,358 duplicate files, 18,831 documents (including Microsoft Word and Excel documents), 246 spreadsheets, 38,415 images, 16 email messages, 6,472 executables, and 7,886 folders. 56 distinct users of the machine are noted by examining the "Documents and Settings" directory. Although 10 encrypted files are indicated, these were just files in the standard Microsoft Office distribution. FTK identified no contraband or potentially dangerous files which matched the latest NSRL or Hashkeeper hash sets, making existence of an existing compromise unlikely. As an added measure for detection of malware, an additional copy of the target drive was made and this drive mounted in a test system running Windows XP. A full drive scan using Norton Antivirus 2004 was performed, but no infected files were discovered.

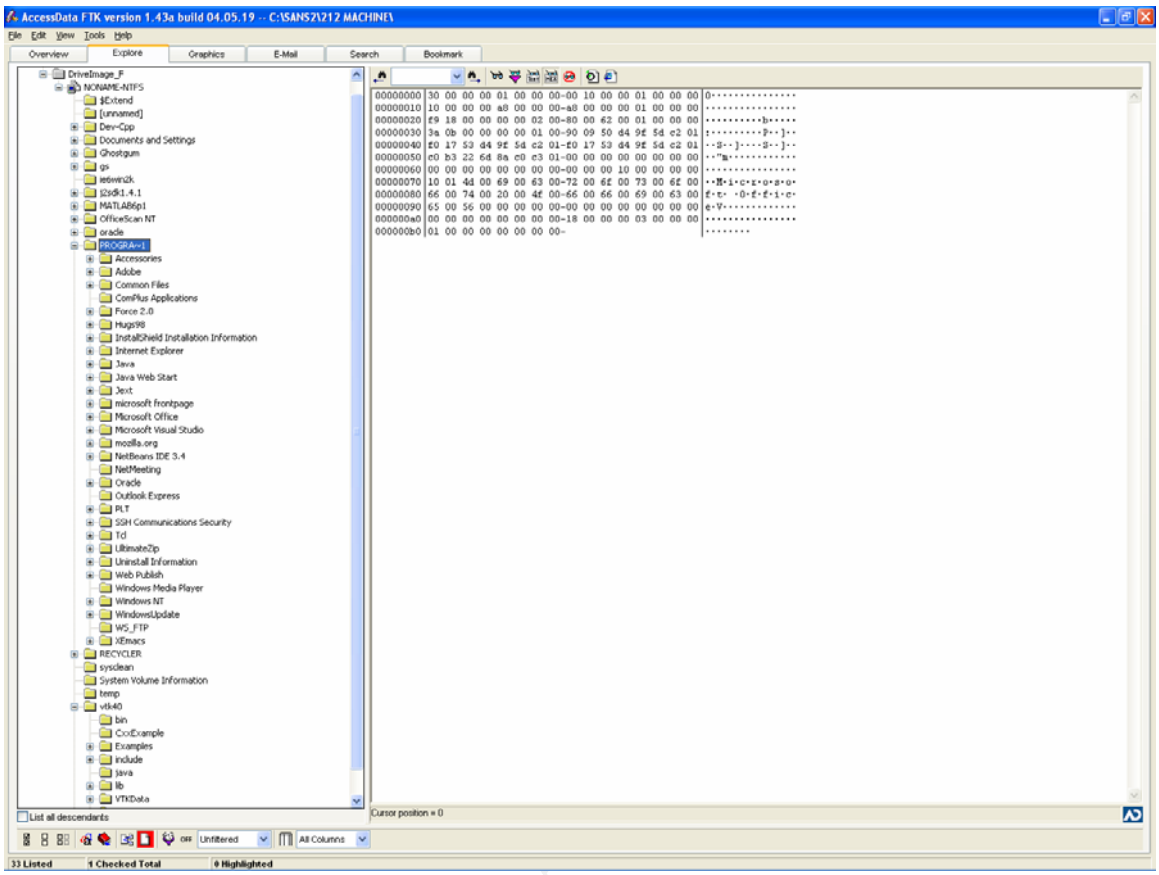
As an initial investigative step, the "Documents and Settings" subdirectory for each user was examined to note any unusual application software or startup folder settings. A description of the contents of each user's subdirectory is omitted due to the large number of users; only significant entries are noted. FTK provides an intuitive graphical interface that allows quick exploration of each of the user's subdirectories, similar to the Windows Explorer window. Evaluation of Internet Explorer history files is deferred for the moment.

The programs installed for "All Users" include the following, captured by examining the Start Menu→Programs directory. None are unusual; they include common development tools used in the laboratory, archiving tools, file transfer and remote communication utilities, and Microsoft Office.



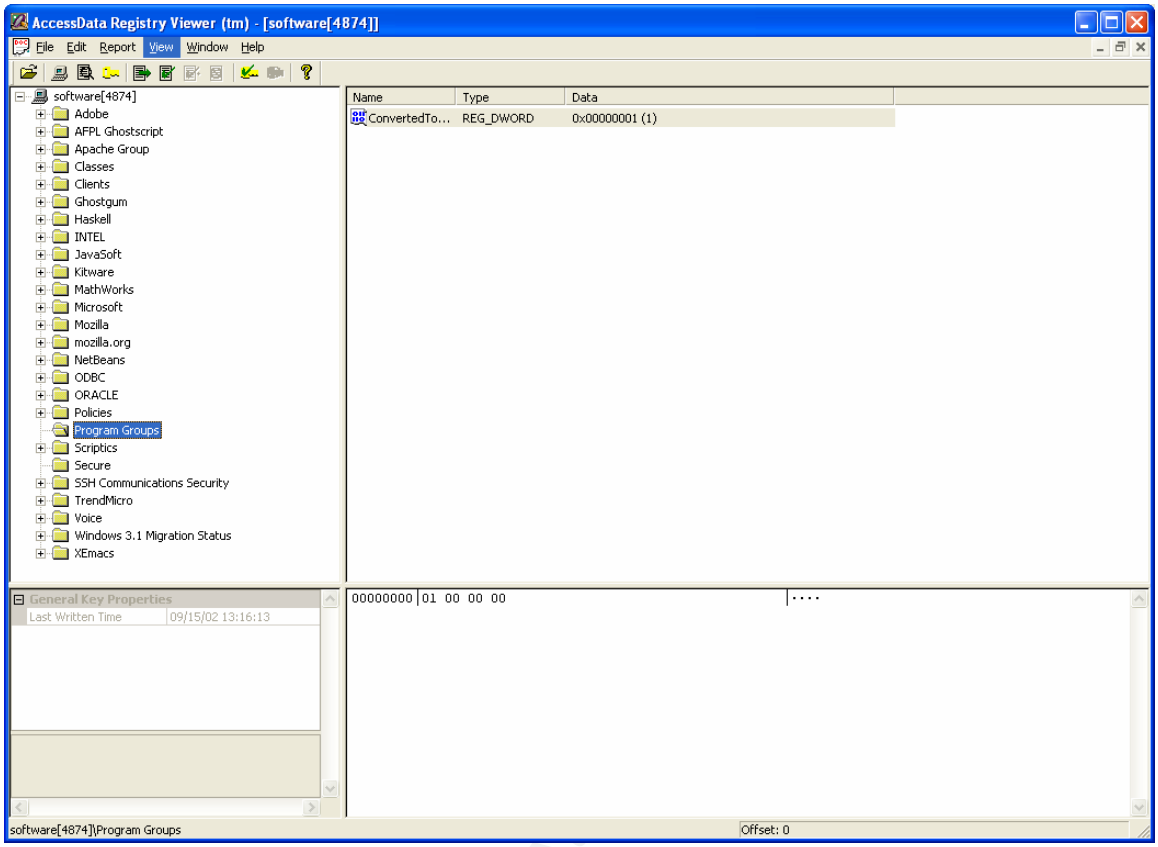
The startup folder for the Administrator account contains one entry: UltimateZip Quickstart; all other startup folders are empty.

The following folders exist in the "Program Files" directory:



All entries are reasonable. A consultation with the systems administrator revealed that the department has licenses for each of these packages (in the case of commercial software) or that the software is authorized for use (in the case of free/shareware).

The top level of the "software" file in \WINNT\System32\CONFIG, a portion of the Windows registry which holds information about installed software, revealed nothing out of the ordinary:



The “ntuser.dat” file for each user was then checked using the registry viewer in FTK. This file reveals information about recently used documents, AIM/ICQ contact lists, and Kazaa configuration information. Of particular interest are the “Software\Kazaa”, “Software\Yahoo”, “Software\Mirabilis”, and “Software\America Online” keys, which indicate installation/use of popular chat/file sharing software. None of the “ntuser.dat” files indicated installation or use of any of these packages.

The print spool directory was checked and was empty.

Use of a local email client (as opposed to using a web-based email client) was very light on the target machine. Several email messages were recovered, but all except one were class-related. One contained a comparison of several laptop computers as part of a student presentation, emailed to the instructor of the course. Others contained queries about whether an instructor had received a particular assignment. The one non-class related email discussed a Ferrari seen on the Interstate:

Message0001	
Subject:	**Ferrari Enzo (02-)**
Date:	Wed, 29 Oct 2003 09:19:51 -0600
To:	<Tracy082@aol.com>
Message Body	

This is the machine that we saw getting on the interstate. Ferrari made less than 400 of these things.
Attachment
-----Attachment2----- File name = “Ferrari Enzo (02-).jpg”

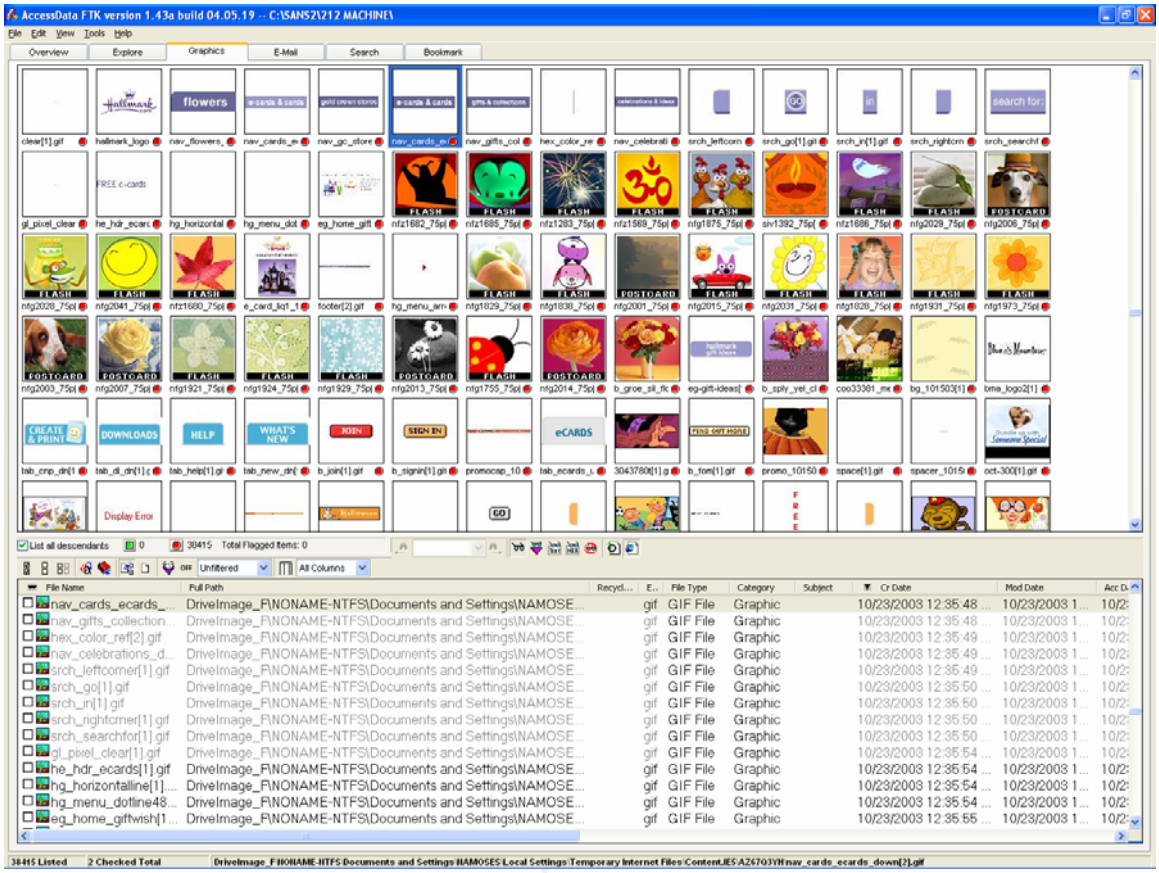
The image of the Ferrari was recovered on the machine separately, based on the filename provided in the email:

Use of the systems in the laboratory for creation of Word documents and Excel spreadsheets, for whatever purposes, are generally allowed, as many students use the lab to create resumes or to write assignments for other courses. These document types were not examined in detail.

The entire directory tree for the imaged drive was expanded and sorted by extension, in FTK. No MP3s were noted. Similarly, no AVI files other than the ones installed by Windows or by commercial applications (e.g., Microsoft Visual Studio) were noted. No MPG files were present on the computer.

The Internet Explorer history files of each user were examined briefly. Buying CDs, viewing family pictures (e.g., stored on webshots.com, a repository of user-created digital photo albums), access to Internet banking, and light usage of online games, such as those available on games.yahoo.com, by one user (name omitted to protect privacy), were noted. Discovery of more forensically interesting material, include pornographic images and illegal software, was deferred until graphics files were examined and keyword searches performed.

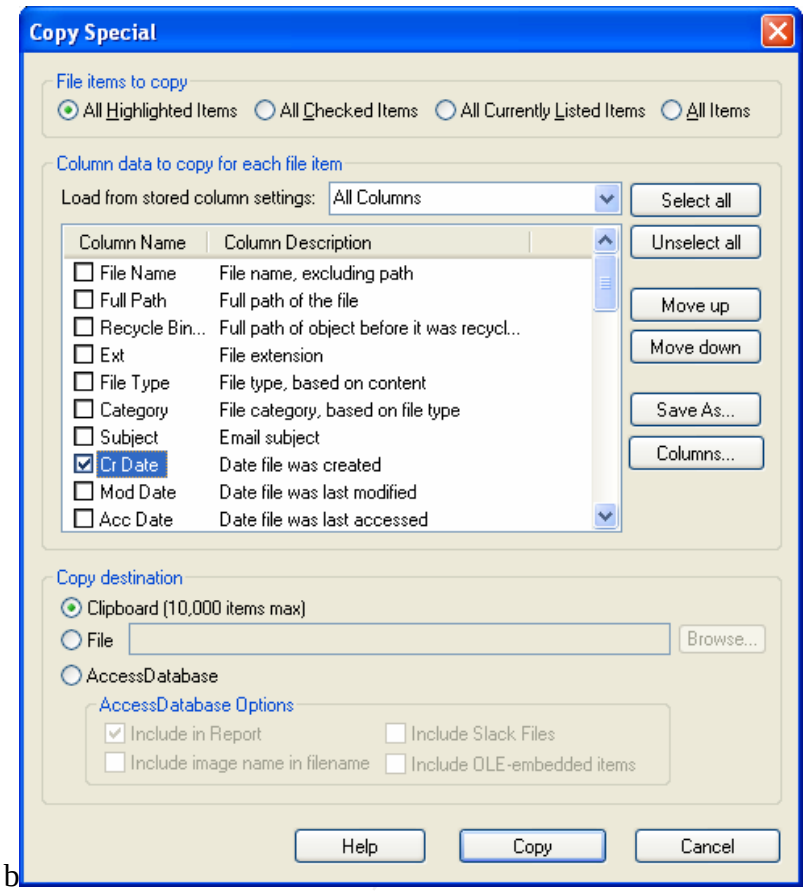
FTK reports 38,415 images total on the drive, of which 27,862 are unique. There have been several reports in the past (by students) of pornographic material being observed in the lab. The graphics thumbnail viewer in FTK was used to identify viewed pornographic content by sorting all images on the drive by creation date and then looking for groups of images that indicated a pattern of surfing for pornography. A screen shot of the graphics viewer in FTK appears below:



With the "List All Descendents" checkbox in FTK checked, all graphic images on the entire target drive can be viewed at once in the graphics viewer. Clicking on an image thumbnail highlights the appropriate entry in the file listing in the lower portion of the window, so creation, access, and modification times, as well as other file metadata, can be noted.

One user, with sanitized username "XXXOSES", browsed a large number of hardcode pornography pictures (> 100 high resolution images were found in the IE cache for this user). This clearly violates the spirit of our acceptable use policy. The user apparently made no effort to delete these images. Original images are bookmarked in FTK and are available as needed. Below, a complete list of these images with associated creation dates and MD5 hashes is provided. The listings were created by highlighting the group of image filenames in the lower portion of the FTK graphics viewer, then right clicking and copying the file info to the Windows clipboard. Any of the attributes of the selected files can be copied. A screen shot of FTK's "copy special" dialog is shown here:

b



First set of pornographic images, generated during a surfing session by the user on 10/24/2003 from 11:17am (system time) to 11:23 am:

Session # 1 (exported from FTK, all images are from directory "\Documents and Settings\XXXOSES\Local Settings\Temporary Internet Files")

```

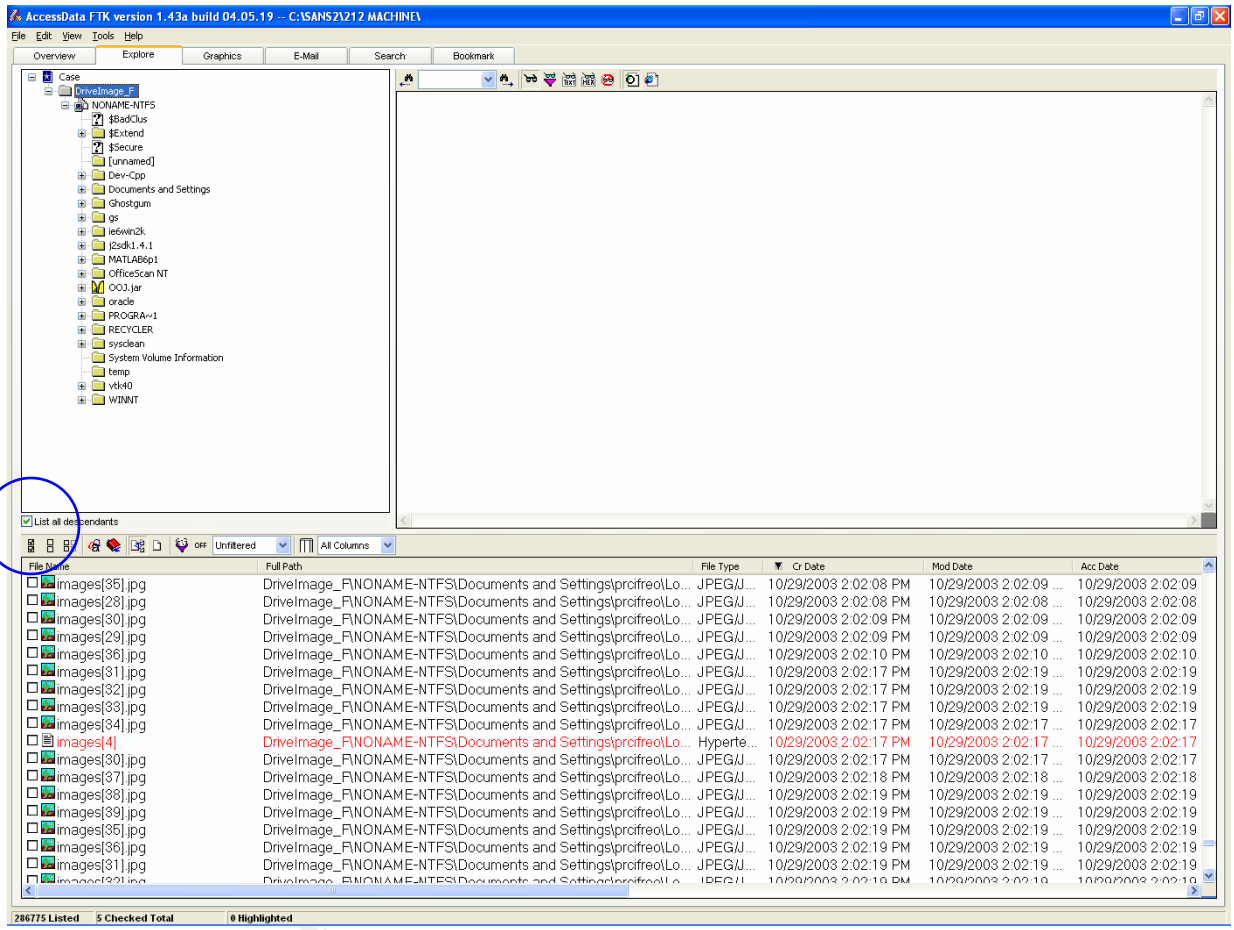
Again, because of the extremely explicit nature of the images, they are not included in the report. Images are available on request.

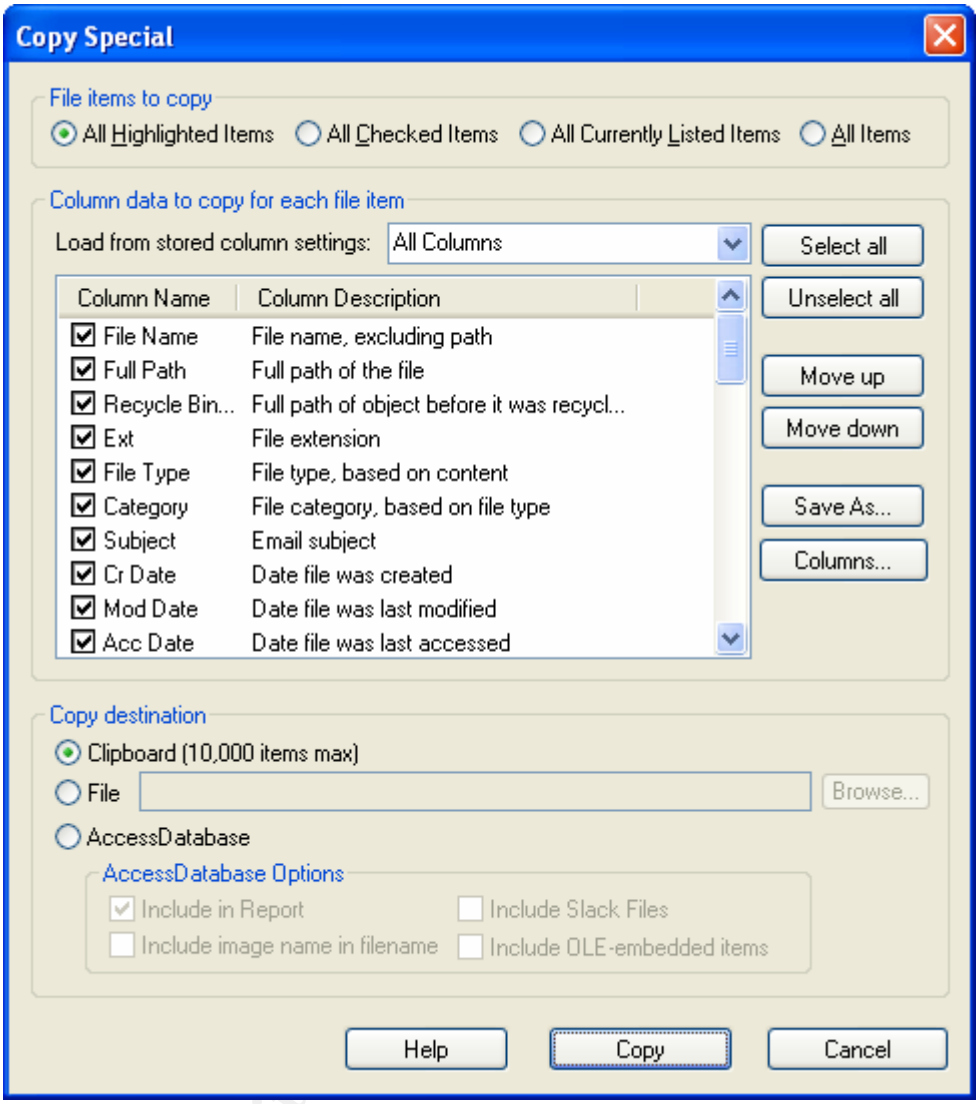
There is no evidence that other users on the machine downloaded or viewed pornographic material. Other groups of images contained anime, science fiction, collections of cellular phones (from an online shopping session), etc.

Timeline Analysis

A complete timeline of the filesystem is omitted in the body of this report due to the large number of files stored on this computer (in excess of 200,000 files). Instead, relevant portions of the timeline are included. Generating a timeline in FTK is straightforward. First, click on the Explore tab in FTK, yielding a screen like this:

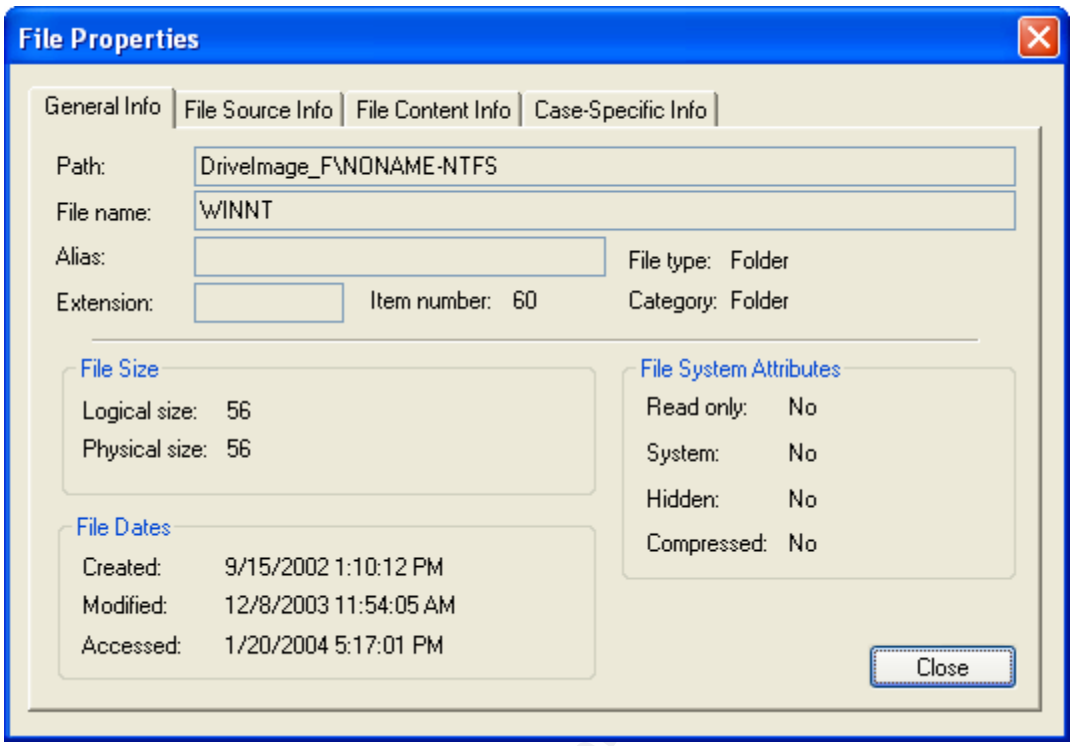


Clicking on DriveImage_F in the tree view in the left upper corner of the window selects the entire filesystem tree. Then, selecting the "List All Descendents" checkbox (circled in blue above, because it's rather hard to see) lists every file on the target drive in the bottom portion of the window. Then clicking "Cr Date", "Mod Date", or "Acc Date" will sort the file listing by creation date, modification date, or access date. The timeline can then be viewed in FTK by scrolling around in the file listing, or exported. To export the timeline, once the desired sorting criteria have been applied, right clicking on the file list in the bottom portion of the window allows the "Copy Special" dialog to be used:



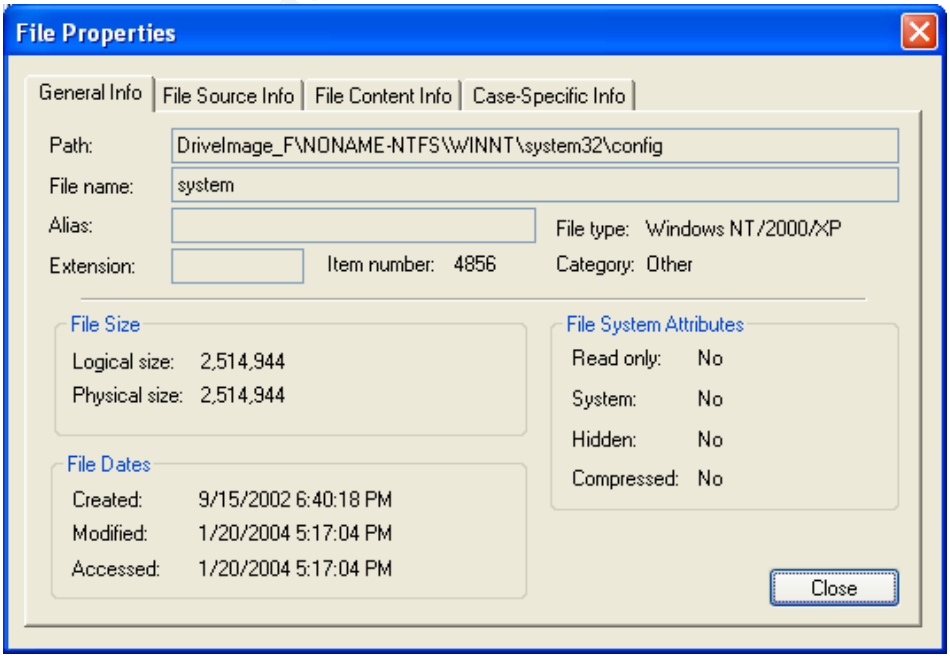
Specific columns in the file listing to be exported are specified using the checkboxes. For example, to export a timeline containing only filename and creation date columns, the corresponding checkboxes should be checked and all other checkboxes cleared. The "Copy Destination" area of the Copy Special dialog allows the data to be exported to either the clipboard, a file, or a Microsoft Access database. For the rest of the timeline analysis in this case, the dates were simply examined in FTK rather than exporting a 'textual' timeline.

The creation date of the "WINNT" directory indicates the initial install of Windows on the box since the last drive format. As seen in the following FTK screen shot, Windows was installed on this machine on 9/15/2002. Examination of creation dates of folders in the WINNT directory confirms this date.



Examination of \WINNT\ServicePackFiles indicates that the last service packs were installed 9/3/2003 at 9:39am Central.

The system was last used on 1/20/2004 at approximately 5:17pm, as shown in the following screenshot, which depicts creation, access, and modification times for \WINNT\system32\config\system, which is part of the Windows 2000 registry. This file is updated during any significant use of the computer.



The following snip of the system timeline illustrates when particular user accounts were created. These names correspond to directories in the "\Documents and Settings" folder. The first three characters of each username have been replaced with "XXX" to obscure the identity of the users.

Tcl                            9/22/2002 5:11:30 PM
WindowsUpdate                  9/3/2003 10:07:19 AM
Force 2.0                      9/3/2003 11:14:00 AM
```

One exception is "Force 2.0", a FORTRAN 77 programming environment for Windows based on the gcc compiler. See [3] for details. This application suite was installed on 9/3/2003.

Expanding the "\Program Files" directory tree and sorting by modification date shows that no files were modified after 9/3/2003, the date that the last application ("Force 2.0") was installed.

Expanding the entire directory tree, targeting only Windows executables, and then sorting by modification time revealed that the only executables with modification dates later than 9/3/2003 were installed by the "sysclean" antivirus software and a single executable downloaded by a user XXXoup (the Google toolbar):

```
PATH: \Documents and Settings\ADLoup\Local Settings\Temporary Internet
Files\Content.IE5\MV25KBKD\GoogleToolbarInstaller[1].exe

MD5: 53E7A71599E6BF7E6A1730C8AD686FD8
```

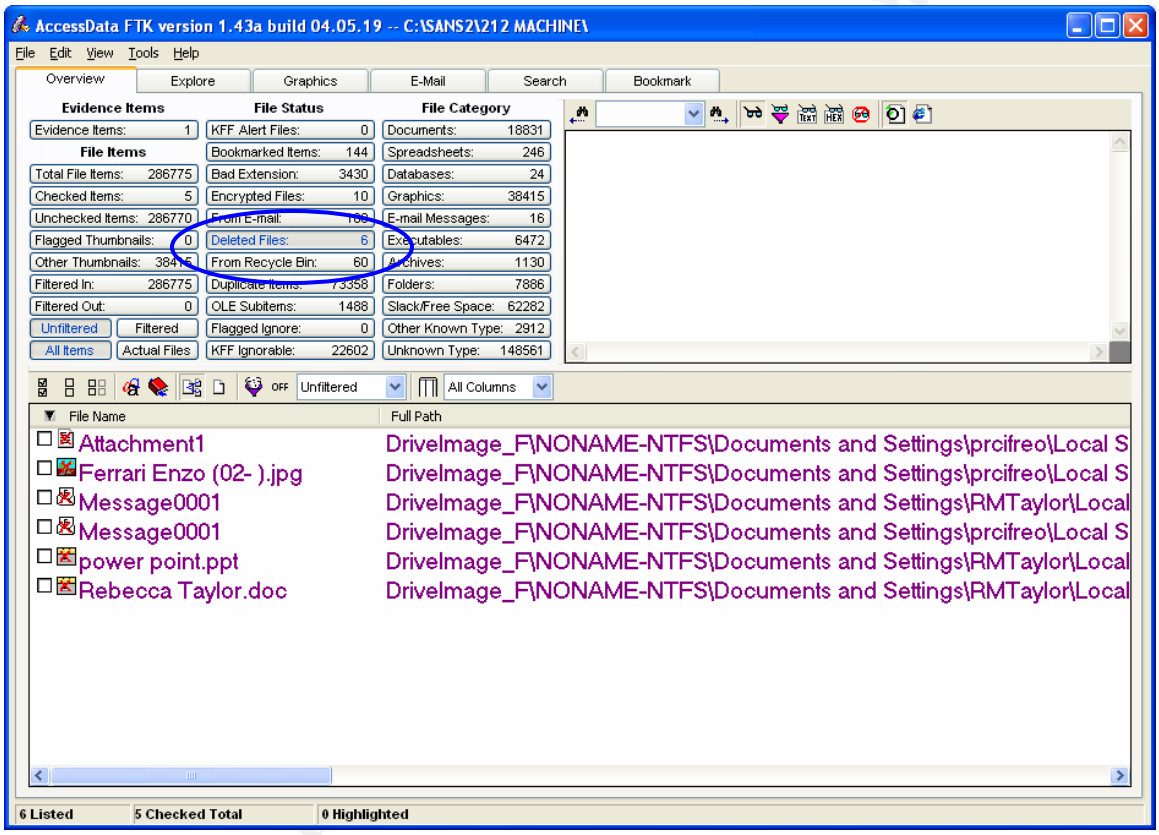
Chronology

Key events in the lifetime of the filesystem on the target machine are summarized here:

9/15/2002	→	Initial installation of Windows 2000
9/15/2002 to 9/16/2002	→	Most applications installed on machine
9/18/2002	→	NetBeans (Java development environment) installed
9/22/2002	→	Oracle, TCL installed
9/3/2003	→	Windows Update installed
9/3/2003	→	Force 2.0 (Fortran 77) installed
9/3/2003	→	Last service pack installed
9/3/2003	→	First user account created on this machine
10/24/2003	→	First surfing session involving large quantities of pornography
10/28/2003	→	Second surfing session involving large quantities of pornography
1/14/2004	→	Last user account created on this machine
1/21/2004	→	Machine taken down for imaging and analysis

Recover Deleted Files

Very few deleted files were discovered on the machine. No additional steps need to be performed in FTK to recover deleted files. Any deleted files that are completely recoverable are recovered during FTK's initial processing of the target drive image, as discussed in the Media Analysis section. All that is required to examine deleted files in FTK is to click the "Deleted Files" tab in the case Overview display:



FTK reports only 6 deleted files, none of which are significant. The first three files discuss the Ferrari Enzo seen on the interstate (see the Media Analysis section for details). The fourth file is a lab submission to an instructor. The Powerpoint and Word documents (files # 5 and 6) are corrupted and not viewable. Viewing these files in ASCII/hex view reveals nothing of interest. 60 files are in the recycle bin, but most of these are older versions of homework assignments. The "INFO2" files which track recycled files for each user under Windows 2000 were examined, but no discrepancies were found—all files listed in the INFO2 files were recoverable directly through FTK. Examining the recycle bins for users is straightforward in FTK—referring to the screenshot above, the tab below "Deleted Files" is labeled "From Recycle Bin". Pressing this tab provides a listing of all recycle bins for all users, including the INFO/INFO2 index files.

To discover other deleted material, file carving was employed. File carving searches for files in unallocated space by matching headers for known file types to identify the beginning of a file (and sometimes footers, to identify the end of a file). For example, all Word documents begin with the hexadecimal string 0xD0CF11E0. Because the structure of a file carved from freespace is lost (that is, the "file" is really just a block of data, not a proper member of the filesystem), file carving software typically locates a matching header and then assumes that the following *n* contiguous bytes on the drive are part of the file. For most carving software, the value of *n* is fixed by the investigator before file carving begins. Files that are fragmented are not easily recoverable using carving, because only the portion contiguous with the header is easily located. Still, even the initial portion of a recovered file may have evidentiary value. Similarly, files whose initial block has been overwritten are very difficult to retrieve, since no matching header will be located. String searches may still yield partial recovery for "textual" file types, though. Because files carved from freespace are not participants in the formal filesystem on a partition, no metadata is typically available. This means that filenames, creation times, modification times, access times, etc. are not recoverable, because this metadata is typically maintained by the filesystem and **not** stored in the data area of a file. File carving software simply makes up unique names for discovered files.

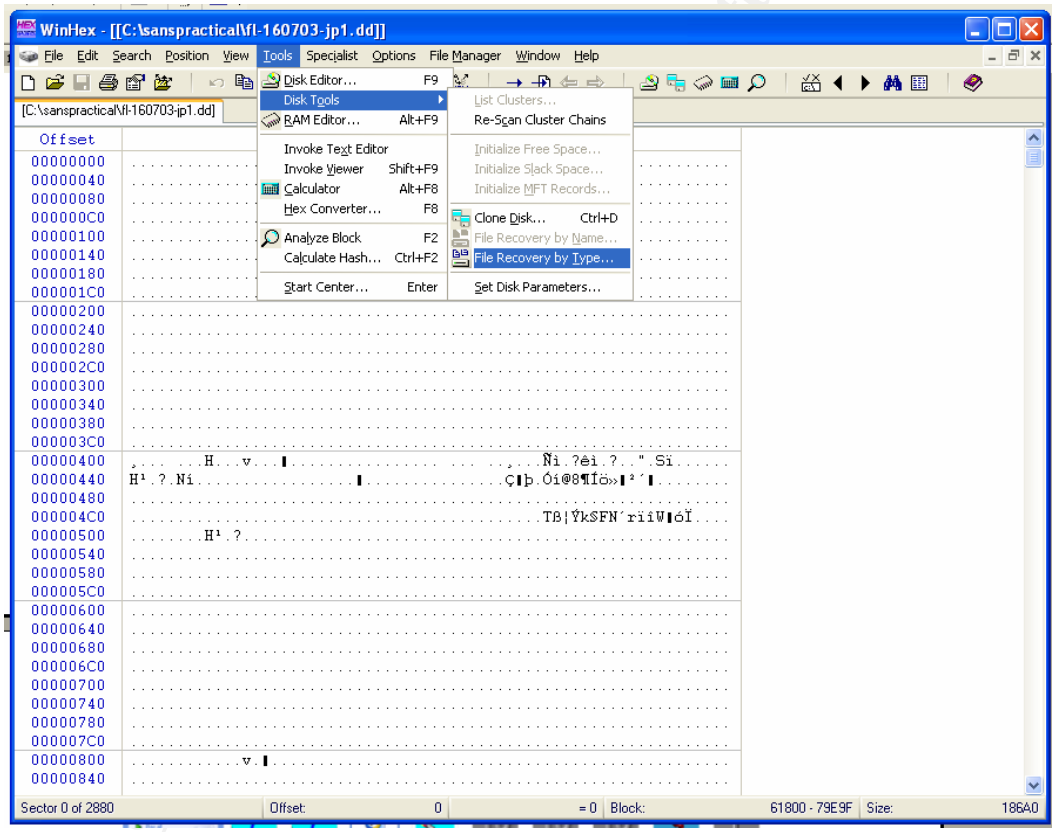
Because FTK file carving is inflexible (covering only a few file types, with no user-definable carving possible), WinHex 1.15 was used on a copy of the drive image. A dd format image was created from the SMART format target drive image using the FTK imager (the FTK imager was discussed in Section Image Media).

WinHex file carving covers the following types, with other types being user-specifiable:

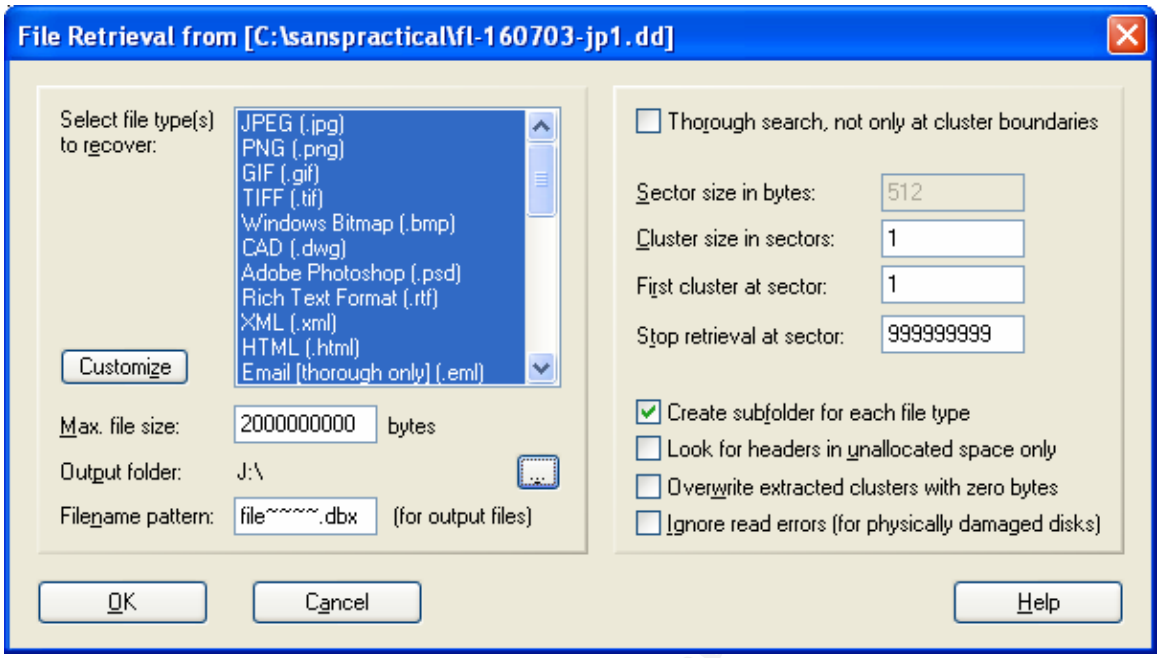
JPEG
PNG
GIF
TIFF
Windows Bitmap
CAD
Adobe Photoshop
Rich Text Format
XML xml
HTML html
Outlook Express
Outlook
MS Word/Excel
MS Access
WordPerfect
PostScript
Adobe Acrobat
Quicken
Windows Password

ZIP Archive
RAR Archive
Wave
AVI
Real Audio
Real Media
MPEG mpg
Quicktime
Windows Media
MIDI

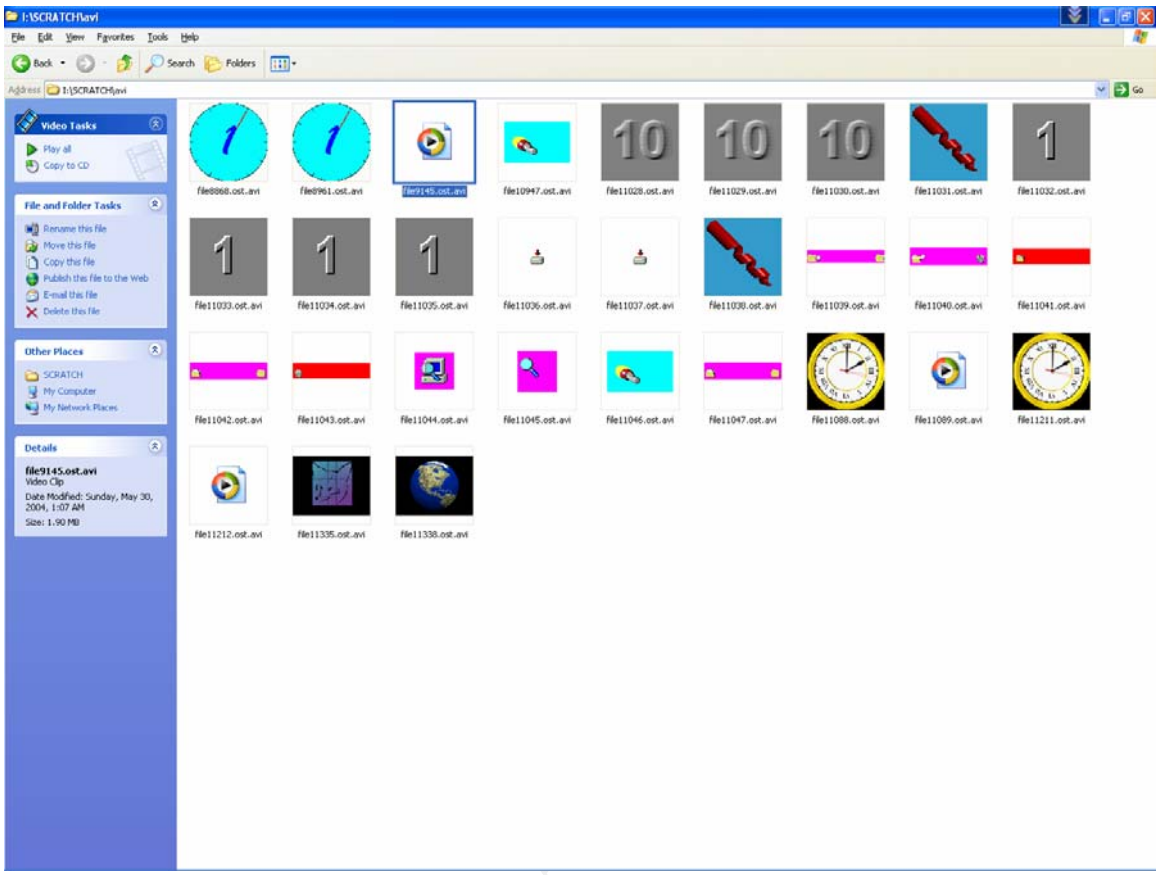
File carving operations are available under the Tools → Disk Tools → File Recovery by Type menu in WinHex:



The file carving dialog allows a number of custom settings, shown in the screenshot below:



A maximum file carving size of 2,000,000 bytes was used, with output directed to an 80GB USB drive (drive J:, as shown in the dialog). All supported file types were selected. Once carving was complete, 16,803 files were carved from free space in the image. The vast majority were .BMP, .GIF, .JPG, and .PNG image files. None of the carved 5 .MPG files were playable. None of the 30 carved .AVI files were significant, though most were playable. Thumbnail view of the recovered .AVI files is provided below:



File carving yielded no recovered MP3s. As discussed previously, no undeleted MP3s were discovered on the machine. Further, there is no evidence that file sharing software was installed on the machine.

753 ZIP files were carved. A script was used to execute the command "unzip –v" on each of the files, to determine if each ZIP file was usable. Only 5 were intact—all of these contained collections of Java class files (note: the files may have actually been Java JAR files, since ZIP and JAR files share a common header).

3 carved high-resolution (> 200x200) JPEGs could be considered "inappropriate" for viewing in the laboratory out of 2,607 JPEG files retrieved. These are omitted because they still exceed PG-13 ratings, but are available on request. No hardcore pornography was noted, providing further evidence that the machine was probably used for viewing of hardcore material by only one user, XXXOSES, as noted previously.

None of the 8,943 carved GIF files had any obvious forensic significance. All were buttons, banners, etc. for web pages.

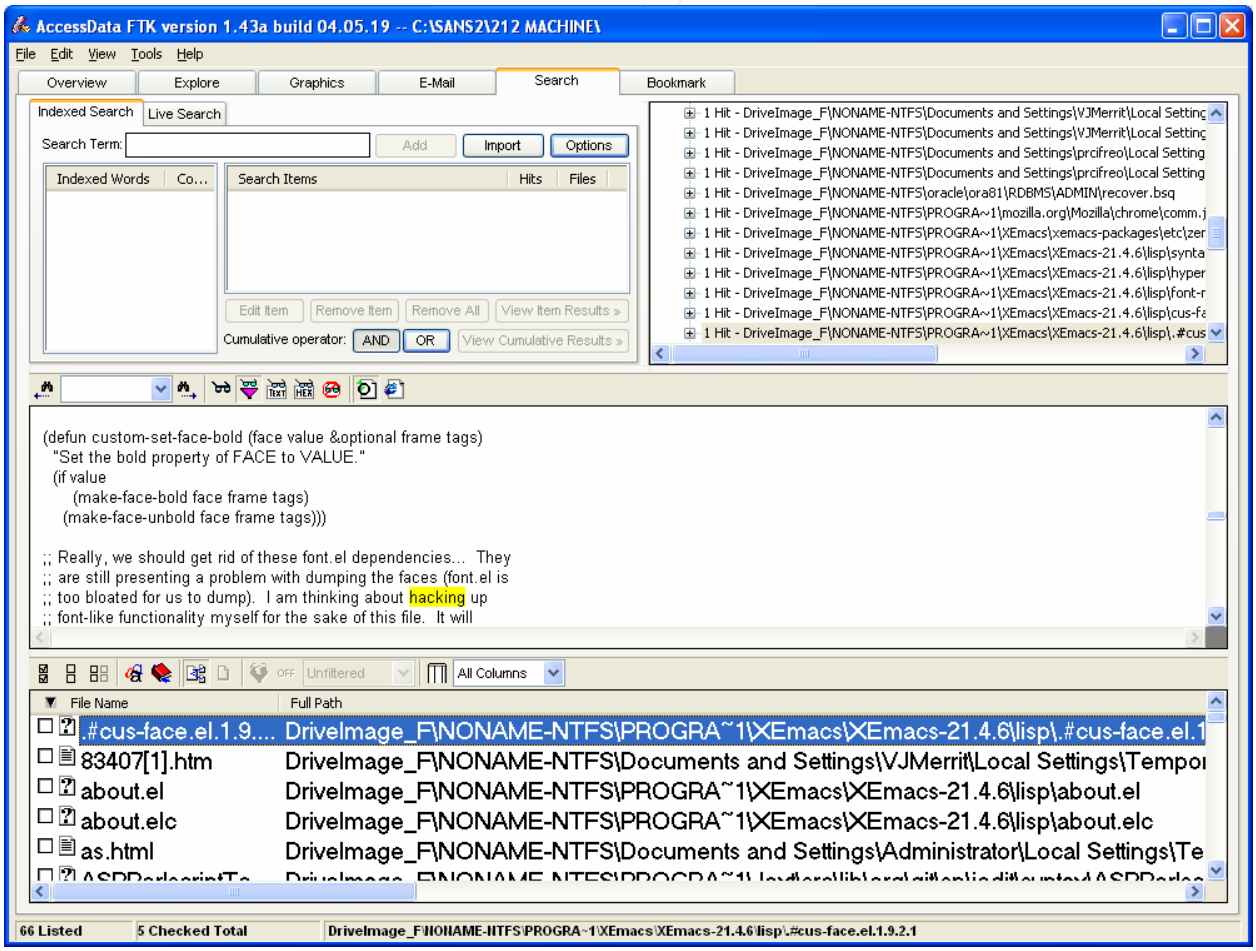
All carved TIF/PNG were random pictures from the Internet (animals, nature scenes, etc.) and were not significant.

The 410 carved Word/Excel documents contained fragments of a speech by JFK, lab assignments, several resumes, and a press release by the Clinton Whitehouse dated Jan. 7, 2000 on cybersecurity.

String Search

Several string searches were conducted against the drive image, using FTK. String searches in FTK take two forms—indexed searches and "live" searches. Indexed searches provide virtually instantaneous results, since FTK built a database of the locations of all the words in the index during initial preprocessing of the target drive. "Live" searching examines the entire drive image in real time, which can be very time-consuming. Live searches must be used for strings that are not in the index and for regular expression-based searches, however.

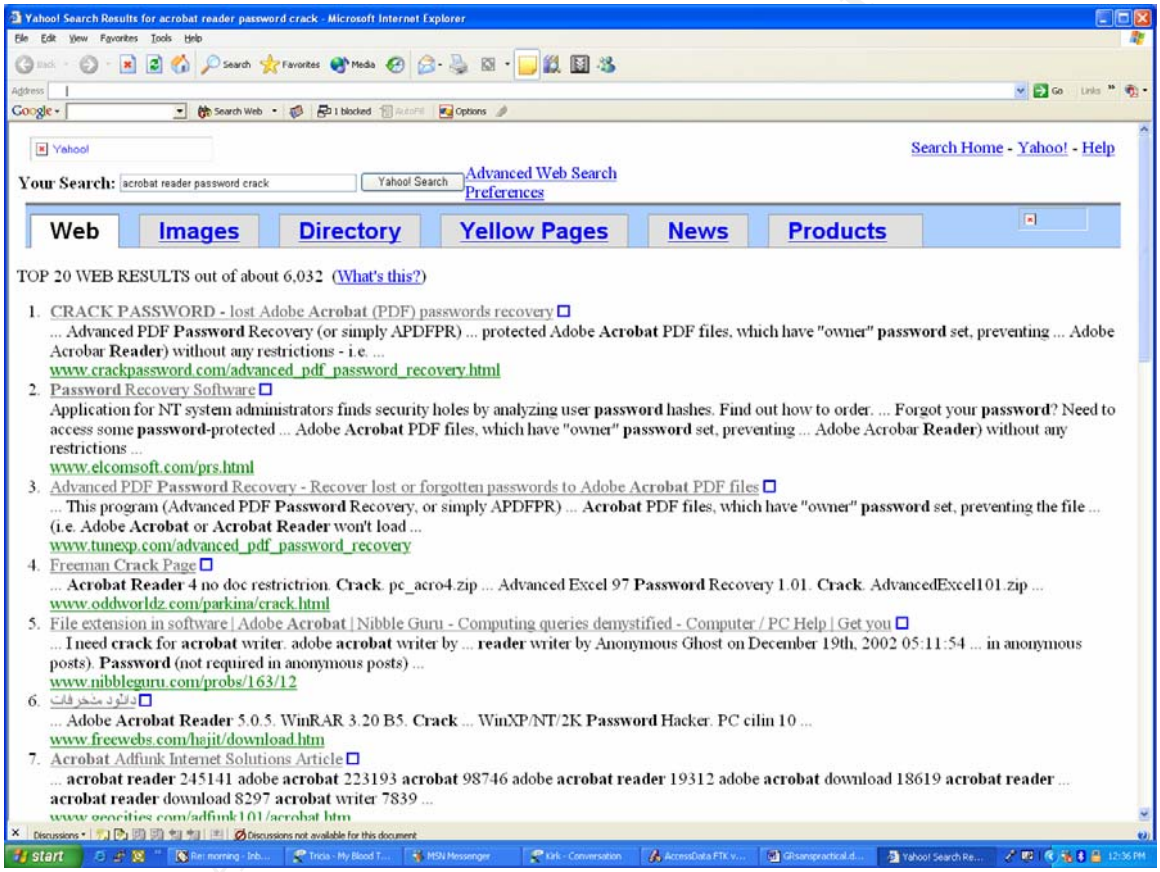
Searches in FTK are carried out using the Search dialog, accessible with a single click from the main FTK screen. The search dialog looks like the following. Search terms can be combined using AND and OR operations. Hits are displayed in the right upper corner, and clicking on a hit displays the match (in context) in the center of the screen:



A string search for “hacking” yielded no useful results—most hits were on XEMACS Lisp files. This keyword was used to see if any documents related to hacking were present on the target.

A string search on “cracking” yielded a hit in free space on a web page fragment describing the FDA “cracking down” on dietary supplements. This keyword was used to see if any documents related to cracking copyrighted software were present on the target.

A search on “cracked” + “download” yielded one hit in XXXerrit’s IE browser cache—a search for a crack for Adobe Reader password protection. This is not particularly alarming. The matching web page is shown below:



String searches did yield some additional evidence of use of the laboratory computers for viewing pornographic images. A search on keyword “porn” yielded 246 hits, most of which were fragments of web pages that looked like popups. One of the hits was on a cached web page that included some of the images by user XXMOSES, responsible for the two extensive sets of pornographic images described earlier. The following HTML fragment was recovered, with creation date 11:21:53am on 10/24/2003, tying it to the images beginning with “banner463.jpg” in the first surfing session, described earlier. Searches along these lines were not continued, because there is now a strong reason to believe that the primary offender is XXMOSES.

While this is clearly the best site on the web ;-), I still like to check out porn at a few other select websites. Here I list the sites that I personally recommend so once you are done here, go to one of these and bust another nut!

Hammer Video	**TEENIE JUNKY**	**Teenie**	**XNXX**

The movie post site I have found.	Great Free teens pictures, and movies.	**Movies** Free Big Movies	Multi Categories Quality TGP

MMM100 great movies, huge archive of links.	**Link Blender** More Free Quality galleries	**The Elephant List** Free pics, movies and huge archive of links.	**World Sex** Natural tits, Round Asses and Cute Girls

Conclusions

Analysis of the machine revealed that, in general, the flavor of the policy document and system banners were adhered to by laboratory users using this particular machine.

Applications were installed on the machine under investigation over a few fixed timeframes. There is no evidence that unauthorized copyrighted software was installed.

The vast majority of the content on the machine was for class assignments. No collections of MP3s or digital media were noted. No online chatting software was detected. Keyword searches and a casual scan of HTML documents in the user's browser caches revealed nothing to indicate that unauthorized software or other copyrighted material such as MP3s were downloaded using the machine, supporting the theory that overall, use of the machine falls squarely within the acceptable use guidelines.

Very few files were marked deleted and very few files were present in the users' recycle bins. This supports a view that the machine was typically used in a "straightforward" manner, with users making little effort to conceal their activities.

No compromises of the machine were evident. FTK's Known File Filter (KFF) failed to detect any known malware. Further, a full system scan by Norton Antivirus 2004 with the latest version of the Symantec virus definitions on a copy of the drive (installed in a test machine) failed to detect any viruses, worms, or other malware.

On the other hand, a single user ("XXXOSES") clearly used the machine to view hardcore pornographic materials on two occasions, as documented in the Media Analysis section. Extensive file carving to discover other inappropriate material failed to uncover any images or other digital media of the sort viewed by XXXOSES, though a few mildly inappropriate images were recovered. These carved images may be associated with the activities of XXXOSES. The failure of file carving to reveal much interesting content (combined with little evidence that a secure file wiping utility was ever installed) supports the theory that the machine was not typically used for viewing pornographic materials.

Part 3: Legal Issues of Incident Handling

Assumption: John Price (from Part 1) was distributing copyrighted material on publicly available systems.

A. Based on the type of material John Price was distributing, what, if any, laws have been broken based upon the distribution?

The Copyright Act of 1976 gives the copyright holder exclusive rights to create and distribute copies of musical recordings (though typically some or all of these rights are transferred to a record company). Distributing copyrighted material violates the Copyright Act of 1976 as well as the newer Digital Millennium Copyright Act (DMCA). Note that even if John Price owns the CDs from which the MP3s were ripped, his distribution of the MP3 is illegal. The First Sale doctrine of the Copyright Act allows the sale or distribution (that is, a transfer of ownership) or destruction of a legal copy of a recording, but the transfer of ownership and possession are closely related. In simpler terms, a recording that one owns legally may be sold or given away once, but the right to distribute disappears once the first copy is out the door.

B. What would the appropriate steps be if you discovered this information on your systems? Cite specific statutes.

John Price is an employee of the company performing the investigation. Assuming that the computer account provided to John is a result of his special relationship with the company (that is, the company would not provide an account of the same type to an arbitrary member of the general public), then the Electronic Communications Privacy Act does not apply and all materials from the investigation can be turned over the law enforcement. This information is taken directly from the GIAC course materials.

C. In the event your corporate counsel decides not to pursue the matter any further at this point, what steps should you take to ensure that any evidence you collect can be admissible in proceedings should the situation change?

The original floppy and drive image must be preserved, along with the investigative notes. A "chain of custody" for these evidentiary items, even in a corporate setting, is best preserved.

D. How would your actions change if your investigation disclosed that John Price was distributing child pornography?

In this event, the entire investigation and any evidence collected would be turned over immediately to law enforcement. Child pornography is contraband in the United States and its possession by citizens is strictly prohibited, thus any further corporate investigation would be inappropriate. The Federal Obscenity Statute (18 U.S.C. § 1462)

and Federal Child Pornography Statute: (18 U.S.C. § 2252) are often used in the prosecution of child pornography.
