Abstract

The following paper will be presented to SANS Institute in order to get GCIH (GIAC Certified Incident Handling) certification.

This paper will be focused in giving information and guidelines about the steps taken in an incident handling conducted by me some months ago, in order to share these experiences and procedures with other security professionals that could be interested in reading about this topic.

The attack or series of attacks covered in this paper were real and occurred inside a company with more than 10000 employees. May be the attack looks like something easy, the exploits used and its consequences, but it is a complex topic to try to fight malware code developed inside a company in order to get private information (login, passwords, credentials, etc.), to use this information in punishable facts.

This paper begins with a detailed examination about keyloggers and other similar malware codes, later reviews a sample and very easy installation of a keylogger in a remote host, the discovery and analysis of this keylogger and, of course, the six steps of incident handling that were conducted to handle this fact in more than 2500 machines.

This paper consists of three main parts, which are subdivided in many others sub-parts. These basic parts are:

- The first section is the analysis and description of the attack committed, including evidence of this discovery and a visionary point of view of the attacker/developer of the exploit.
- The second section explores the attack process, focusing in explaining in detail how the exploit was used, its variations and some speculations about the attacker's methods based in the network topology, operating systems, and other parameters.
- Finally, the last section shows the Incident Handling Process that was conducted covering the phases of preparation, identification, containment, eradication, recovery, and of course, lessons learned over the attack.

All the software that I used for the analysis of the systems affected is a free and open source. In the paper that I will present below, I included enough information sources where the reader can found a lot of information about the software and its use doing malware analysis. The reader can download from Internet all the software that I used, going to the official sites that I indicate.

1. Option II. Incident Handler Case File

In many situations, a displeased employee ran some exploits and malware¹ code against systems in the company where he worked in order to create chaos and any kind of loss (not only economical), using, probably, social engineering and may be any information and software found in Internet. A detailed example of a similar situation was described by Heather Kratt in his paper “The Inside History: A disgruntled employee gets his revenge²”.

The situation that I had to handle was not a disgruntled employee, but a group of employees that developed some malware codes to get confidential information about users in the company, to use it to commit frauds and a kind of swindle causing a great economical loss to the company.

1.1. Part One. The Exploit/Attack

1.1.1. Synopsis of Case Facts

An important telecom company dedicated to the mobile industry, was suffering a lot of complaints from some of his employers dedicated to its financial department, about phone lines that were being activated for someone with the user's id and the password of other users, illegally. This history was increasing and increasing due to the lack of logs that could have registered the source IP from where these phone lines were activated.

To activate a new phone line now, it is used a system that we will call System_M in the rest of this paper in order to protect the identity of the company. System_M is a proprietary system developed by the same company that allows activating, managing and inactivating phone lines that are assigned to cellular phones. The users of this application who can activate new lines are the sellers, located generally in the commercials shops of the company, commonly disposed in shopping centers, exposition centers, etc.

Other group of users is the “Administrator Group” of System_M, that have the possibility to activate, manage and eliminate lines, plus permissions to create, manage and delete accounts used in this application, and in general, management of all the features of the system.

The principal problem was that there had been appearing phone lines activated by users that did not recognize this fact, and said they did not do these activations. For this reason, the administrators supposed that probably the user's id and the password of some users had been used for other persons illegally.

¹ <http://www.webopedia.com/TERM/M/malware.html>

² http://www.giac.org/practical/GCIH/Heather_Kratt_GCIH.pdf

With this supposition in mind, the administrators programmed the System_M to force a change of the password for all the users each two days for the criticism of the information, in order to minimize the stealing of the passwords of the affected users.

However, the situation was continuing, and therefore also the usurpation of users and passwords. 70% percent of these passwords usurpation were being located in users from two or three specifics commercial shops around the country. For this reason, the Financial Manager, *two months* later of the first illegal activation, called the security department of the company in order to discover the group of culprits of this unusual and fraudulent fact.

Before this fact, the company had never suffered a fraud using System_M.

1.1.2. Name of the exploit/attack

Some malware codes were used in order to get the users and the passwords of the users of System_M. These codes were identified as keyloggers applications. A keylogger, as it is defined in³, "is a type of surveillance software that has the capability to record every keystroke you make to a log file". Many of the keyloggers that exist are recognized by antivirus and antitrojans applications, however the last updates of these applications did not recognize the keyloggers found in the systems.

The names of the found keyloggers, detailed below, were:

- Symantec.exe
- UpdateNT.exe
- twain.exe

Note that the names of these files could be identified as normal processes or applications, installed in a typical computer, for example, Symantec could be associated with the antivirus Norton, office.exe could be associated with Microsoft Office, and in this way each one of the other files.

This type of attacks and exploits are not covered by CVE⁴ because they do not apply to a security vulnerability of a specific system or a security exposure. It simply is software that allows recording every keystroke to a file, but it is not attempting against the normal operation of an application or a system. Even finding "keylogger" in the main site of CVE are 0 CVE entries or candidates that match my search.

Although there was no technical vulnerability, a procedure violation and vulnerability existed in all the systems of the company, because against the ethics

³ <http://isp.webopedia.com/TERM/K/keylogger.html>

⁴ <http://www.cve.mitre.org/>

code, policies and processes (including background checking of employees), some persons had installed applications not allowed in these computers.

1.1.3. *Operating Vulnerable Systems*

All the operating systems that allow to run .exe files are vulnerable to these codes, however these applications store the keystrokes to a text file located in the path :/winnt/system32. Only Microsoft Windows NT, 2000 and 2003 with any Service Packs, have this folder by default, where are saved many files of the system.

Microsoft Windows 98 and Microsoft XP do not have this folder by default, so, if the keylogger is installed in these systems, it will not store any information in any file.

It is an easy procedure to use a hex editor to do a change in the folder destination where will be created the log file.

1.1.4. “Vulnerability or Protocol” Description

As I mentioned in section 1.1.2, although no technical vulnerability exists, a procedural violation and vulnerability existed in all the systems of the company, because fighting the ethics code, policies and processes (including background checks of employees), some people had installed applications not allowed in these computers.

The importance of identifying these type of applications is fundamental in small, medium and big organizations that can be victims of employees or persons that have developed proprietary codes, in order to get confidential information about the organization to use it in many ways, violating and evading all the physical and logical security devices (firewalls, IDS's, antivirus, etc.). The sign of these codes are not identified by any antitrojan or antivirus application due to is a specific code, not published in any place.

The vulnerability that was and can be exploited with these types of codes, have correspondence with the proactive and defensive measures that implement the security team over all the equipments of the company, to avoid new installations of applications not allowed, and others processes running, different to those typical and specified in the internal policies.

To fight against this exposure is really a very hard task, it even is easier to design, get, and apply a group of security equipment (firewall, IDS's, etc.) and policies applications than control the applications installed by users, much more when the company is a large corporation with many employees, and probably many headquarters with many departments, including a development software department, for example.

All the employees, when they start to work in the company, sign a “Code of Ethics” that in many of its sections forbid the installation of applications that attempt against the integrity and confidentiality of the company. With these type of applications the employees involved in this fact broke this code, originating a procedure vulnerability.

It is very probable that many lectors that read this paper now will be alerted over these type of facts that did not imagine before, or simply, before then they did not have the knowledge or tools to fight against it. In section 1.2.4 I will explain it.

1.1.5. Attack/Exploit Description

This case was not resolved in a few hours or days. The process followed this timeline:

- June, 2004: There were found in some computers the applications Symantec.exe and UpdateNT.exe.
- August, 2004: It was found in some computers the application twain.exe.

Late October, 2004, some procedures were applied to avoid new incidents which will be discussed in following sections.

The applications found during all the investigation were four .exe files which were:

- Symantec.exe: was an executable file that, copied in the folder Start Menu – Programs – Start Up, is executed each time that the machine reboots. After an exhaustive analysis, described in the next sections, Symantec.exe makes a call to UpdateNT.exe file, located in another path.
- UpdateNT.exe: was an executable file that generally is copied in path /winnt/system32 and once executed, created a task called Update Windows SP1, as can be seen in Figure 1. In Figure 2 it can be seen the name of the process associated with this task. This application stores all the keystrokes in a file called archivo.txt (archivo is the translation of “file” in Spanish), located also in path /winnt/system32.

Tarea	Estado
Update Windows SP1	Activo
Microsoft Word	Activo
C:\WINDOWS\system32\cmd.exe	Activo
Bandeja de entrada - Outlook Express	Activo
Calculadora	Activo

Figure 1. Task Manager – Applications running

TBMon.exe		00	276 KB
TrayApplication.exe		00	284 KB
UpdateNT.exe		01	2,684 KB
UpdaterUI.exe		00	384 KB
vmnat.exe	SYSTEM	00	360 KB
vmnetdhcp.exe	SYSTEM	00	48 KB

Figure 2. Process of system probably comprised

- twain.exe: it was the 2nd version of UpdateNT.exe, but with a similar performance and functionality. Some parts of the code were modified, to avoid that the antivirus signs detected them if they were installed. The changes made can be seen doing a comparison with diff command, as it is detailed in section 1.3.2; twain.exe stores the gathered information in a file called mail, also located in /winnt/system32/. Twain.exe was found directly in folder Start Menu – Programs – Start Up, and did not need any other file to make the call, like Symantec.exe.

All these applications were developed using Microsoft Visual Basic. This could be discovered opening each one of them with khexedit. “khexedit” is a hex editor for the “KDE environment”⁵, and looking at some entries that are associated with applications written in this language. A detailed explanation of this point can be read in section 1.3.2.

Taking this into account, we can think that the developer was not an expert in this topic. Additionally, the structure of the code denoted that it was developed without professionalism.

1.1.6. Exploit References

The keyloggers are applications that have been used for many years ago to capture important data without the victim knowing the fact and the stealing of this information.

The first keylogger that I found were Symantec.exe and UpdateNT.exe and they were reported to many antivirus companies being the first response received from McAfee AVERT, identifying it as a Keylogger-Personal. However, not much information is displayed in their website http://vil.mcafeesecurity.com/vil/content/v_126414.htm, about this malware. Nowadays they can identify it.

The website of VirusTotal allows identifying an unknown file to determine if it is a virus or not. The result of this test over UpdateNT.exe can be seen in the link http://www.virustotal.com/flash/respuesta_sav/resultado?b5616d4eb8f6f8212fdeb c6f65fcc1ba:eng

⁵ <http://home.online.no/~espensa/khexedit/>

The result of this test over Symantec.exe can be seen in the link
http://www.virustotal.com/flash/respuesta_sav/resultado?77f72d26d99d8703eea006ad3a83f999:eng

The result of this test over Twain.exe can be seen in the link
http://www.virustotal.com/flash/respuesta_sav/resultado?389251ceb4fdb494cb2c8dc5abe5659b:eng

Based on this information, the reader can investigate in the website of each antivirus company, finding them by the name put to each one.

An important reference about the programming of keyloggers and its development using Microsoft Visual Basic is a Google Search
<http://www.google.com/search?hl=en&q=keylogger+visual+basic>. Probably, the original developer had used a similar query in his development.

1.2. Part Two. The Attack Process

In this section, I will explain the attack process, segmenting it in several parts, in order to recreate the procedure taken by the attacker to obtain the required data and to gain access to the systems.

In order to protect the identity and confidentiality of the company where it was committed the act, they will have to sanitize the name of it, and many other related fields like IP addresses systems and DNS names.

I will present a short diagram of the network, trying to do it as real as possible; in this diagram I will enhance the points of the network that helped to commit these types of attacks.

1.2.1. How the exploit works

These types of malware codes, like keyloggers or any others of this sort, generally do not exploit any vulnerability in the system, as they only are programs running (generally in the background and invisible mode), that function as a simple and ordinary application, capturing information and storing it in a repository file. However, this fact is very, very dangerous to an organization, because this repository file could be obtained and read to obtain crucial and very confidential data, which can be used as input to commit other facts that will produce important losses to the company.

The malware codes that I found in several machines in the company, only stored some titles of active windows and all the information that was entered using the keyboard. The computers where were installed these applications were used to access System_M, that as I explained in 1.1.1, is used by employees that activate,

inactivate and do changes in parameters of the cellular phones lines, like rate plans, personal data, etc.

The users ID's format used by System_M is particular and for this reason it is very easy to do a filter using regular expressions on the repository file, to discard all the other data, irrelevant for obtaining the necessary information to access the system.

Remember that the first application found was the pair Symantec.exe, located at Start Menu – Programs – Start Up. When this file was found, I used my resource kit for Microsoft Windows, that I always carry with me, specifically the command dd for windows (dd copies bit to bit from a location to other), to create an identical image of the disk to another disk in my laboratory, in order to analyze this file in a laboratory environment. I used my resource kit and not the traditional commands included in Microsoft Windows because it could be comprised by the attacker and cannot be trusted.

Additionally, once mounted the image generated in an environment laboratory, also using my resource kit, I calculated the MD5 value of the disk and compared it with the copied file, using for it the command md5sum (md5sum, compute and check MD5 message digest).

Once done it, the first step taken in my laboratory, composed in this opportunity by a computer laptop with Fedora Core 1 with the last updates, was to identify the file Symantec.exe using for it the file command (file determines the file type).

The file in effect was an executable application as I suspected. The next step was to use the strings command (strings prints the strings of printable characters in files) to look for possible words or phrases that could associate this file with any sign. The Figure 3 is showing some words that allowed to associate that the application was developed using Microsoft Visual Basic, particularly by the following phrases:

```
C:\Archivos de programa\Microsoft Visual Studio\VB98\VB6.OLB
VB5!
VB6ES.DLL
Form1
__vbaFreeVar
__vbaEnd
__vbaObjVar
__vbaLateMemCall
__vbaVarSetVar
```

Figure 3. Some words found doing strings on the application

These phrases are directly associated with applications developed using Microsoft

Visual Basic, however this is not an indicative there is any suspicious thing.

My next step was to use khexedit to analyze the content of the file looking for any sign that could tell me what did the program do.

Looking line per line, as can be seen, I found at sector 0x1860 of the file the phrase "WScript Shell | HKCU\Software\Microsoft\CurrentVersion\Run\RundllShell < c:\winnt\system32\UpdateNT.exe.

This particular line was an indicative that using the registry key, RundllShell was called and invoked the file UpdateNT.exe, located in c:\winnt\system32.

I went to the image where I extracted Symantec.exe and calculated the MD5 value and copied (using the same method described above) the file UpdateNT.exe, located in c:\winnt\system32\ to an USB drive.

In my laboratory, using file command again, I identified the file as an executable application.

I opened it with khexedit and analyzing it line per line I saw, at sector 0x1550, a line that indicated a phrase equal to the name of the analyzed process, "Update Windows SP1". This can be seen in Figure 1.

Continuing the examination, I saw functions called by using Visual Basic, like GetActiveWindow, GetKeyboardLayout, __vbaFreeObj. Starting in sector 0x2020, names are indicated by some keys like BackSpace, Enter, Shift, Numpad. At sector 0x22C0 it was possible to identify a phrase mentioning "archivo.txt Fecha – Hora".

The rest of the file did not indicate any other suspicious sign. I went once again to the original computer, looking for a file called archivo.txt (archivo is the translation of the word "file" in Spanish) and found one in the folder c:\winnt\system32. I copied this file to my USB drive using the same procedure described above, and in my laboratory identified it as a simple text file. The size of this file was very large, close to 30MB. I opened this file with a text editor and analyzing it I observed that it was composed by many tags like "Fecha – Hora", and in the next line a keyboard capture. An important group of these captures were login and passwords of System_M's users.

With this discovery it was possible to note that any person having access to this file could do log-in in System_M using the credentials of any other and do actions and commit frauds without showing his/her real identity. This was an important discover, because the impersonation of the users that appeared as activator of illegal phone lines, was clarified.

Doing a resumé about how the exploits work, each time that a computer using

Microsoft Windows is started, all the applications located at Start Menu – Programs – Start Up are executed. In some computers of the company an application called Symantec.exe was installed, that once executed did an execution of other application called UpdateNT.exe located at c:\winnt\system32. This application is not visible to the user but adds a process task that can be seen using the task manager of the operating system, called “Update Windows SP1”, as was shown in Figure 1, that is used to confuse the user and appear inoffensive. This UpdateNT.exe grabbed all the keys that are entered by the keyboard and stored this information in a file called archivo.txt, also located at c:\winnt\system32. The attacker entered the system using NetBIOS and extracted the file that could contain sensitive information, like account passwords, that later are used to commit fraudulent acts.

The second keylogger (twain.exe) did the same, but stored the data in a file called mail.txt, located in the same folder c:\winnt\system32\|. This keylogger was placed directly in Start Menu – Programs – Start Up and did not need any other program in order to execute it.

1.2.2. Description and diagram of the attack

At the moment in which the keylogger was installed in the affected computers, the Administrator passwords were the same in most of them. Additionally, many of the computers by default started with the folder C\$ and ADMIN\$ shared, merging these two factors. Any person knowing this password and knowing the IP address could copy or open the file from this location and obtain the user ID and the password in System_M of the user, owner of the computer.

These keyloggers were installed in commercial offices of the company where the selling of the phone lines were done.

The diagram of the network, at the moment of the installation of the pair Symantec.exe and UpdateNT.exe, showed several computers added to a big hub. With this topology, once detected the first keylogger and thinking that possibly there could be others installed, I placed three computers HP Proliant 320⁶ Pentium IV 2.2 GHz, 1 GB RAM with a hard drive of 80GB running Windows XP with NTFS as filesystem and Ethereal for Windows, connected to the backbone of each of three commercial offices affected before with the keylogger, in order to capture all the illegal and irregular access to the computers, in order to discover the machine source from where the transfer of the file could be done, and in this way the culprit was caught.

The structure of the net of each commercial office with the sniffer was the one shown in Figure 4. The commercial offices had close to fifteen machines connected to a hub where I placed the sniffer. Nowadays are connected to a switch in order to reduce the collisions and avoid precisely possibly sniffing to

⁶ <http://h18004.www1.hp.com/products/servers/proliantdl320/>

capture data.

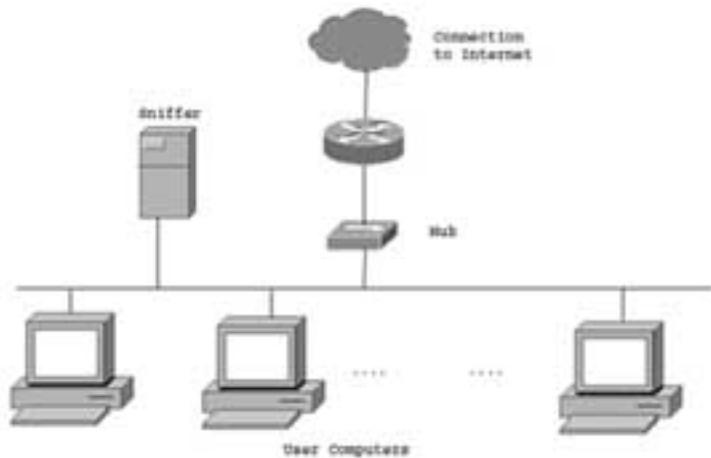

Figure 4. Net configuration of the commercial offices

1.2.3. Signature of the attack

The signature of the attack that effectively is shaped simply by an executable file that is running in a “transparent” mode, is already detected by most of the antivirus applications. The signature that I will show in this document is the content of the “extra.dat” file submitted by the Virus Research Division of McAfee AVERT, an “extra.dat” contains the signature of the possible virus, identified when a person or system submits a virus example to this division. This file should be copied into the directory where the other DAT files reside. It is easy to encounter this path using the find/search utility on a computer searching for the file scan.dat, for example.

The content of the extra.dat that identified the first malware code can be seen in the Figure 5.

```

82 178 159 178  77  51 198 214 116  95 226 212  32  99 232 193

```

Figure 6. Signature to twain.exe

New signatures could be developed to particular IDS's softwares that could identify transfers of particular files through the network. For this reason I am adding the hexadecimal content of each one of the malware codes found in Appendix section 1.4, 1.5 1.6.

1.2.4. How to protect us against them

The protection against malware code developed inside a company, is really very, very difficult, because there are no anti-virus, no anti-trojan, no anti-whatever that could detect these new threats, as it is not a public code that affects thousands or millions of systems elsewhere, only affecting a few machines that are inside a private organization and have not been spread to many computers.

The recommendation, when a security team finds a malware code inside his/her organization, is to submit a sample of this code to the major anti-virus, anti-trojan companies, so that this new code could be identified automatically with the next signatures update.

In the case of the codes that I explained above, most of the antivirus at present recognize the applications mentioned above as a virus program and as soon as it is executed or copied to any disk of the machine, it is deleted and an alert is showed on the screen to the user.

An important phase in the protection is to try to identify and discover new malware

codes installed in the computers of the companies. For this reason, periodically tasks are running, which identify the applications that are called when any machine starts. This process consists in checking the entries found in the location Start Menu – Programs – Start Up, and all the entries located in the registry key HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run. This is a hard task due to the large quantity of machines that have the organization and the heterogeneous applications that store each user.

These procedures not offer the guarantee that any malware code could be named as a recognized application and escape the attention of the procedures that check it, but the security team is working in an application that checks the hashes of the recognized applications against the hashes encountered in the analyzed computers, however it is not ready yet.

For the moment, all the computers are vaccinated against these malware codes found by us, and periodically the signs of the antivirus clients in all the machines are automatically updated.

Also, the security team is training all the employees to review and check abnormal behavior of his/her machine, and to check possible new processes in the process table that could be suspicious. We have been receiving many false positives, but these are actions that are important to maintain, because, with the help of all the employees, new malware codes could be detected and fight against them as soon as possible.

1.3. The Incident Handling Process

1.3.1. Preparation

The malware codes were found in different times and in different machines. For this reason I need to explain the details of each one and the steps taken in order to handle the incident. The first step was to identify some users that could be involved in identity usurpation. I chose one of these users and got his computer in order to do an analysis of it without shutting down the machine and later doing a bit to bit copy of its hard drive (generating an image of the disks).

The perimetral security in the company was very good. The company had good firewalls, good IDS' systems and a dedicated and trained staff to maintain and apply new changes in these equipments.

However, the security policies that existed in the company, applied to users' computers, were not the most idoneous, and although over more than 98% of the machines were connected to the network and maintained its security patches and antivirus signatures updated automatically, many of them had weakness in access control. An example of this is that many of the computers had the same and "universally known" administrator password. Other situation is that not all the

computers had a personal firewall installed; it did not exist a formal specification about user profiles, etc.

For these reasons, to commit an attack in this moment was very easy, not only strong attacks like DoS or BoF, but simple attacks like robbing information (because the password was the same, for example), files changes etc. In brief, although strong perimetral architecture existed, internal attacks were very easy to commit.

By then, it was not conformed a strong Incident Handler Team (IH) or a Computer Incident Response Team (CIRT). It only existed security staff that could be involved in an incident handling, fighting against a worm or a simple attack, but not all of them had enough training and knowledge to carry an effective incident handling. All the security staff was formed by persons with many skills and cleverness (some of them were certificated CCNA, CCNP, CISSP, MCSE, etc. and with a lot of knowledge), but they did not follow any formal procedure according to the company, because it simply did not exist.

This staff mastered perfectly many security terms and concepts, even having developed applications that reduced the security threats of the company and improved real solutions to many problems, but regrettably they had been working for a short time (4 or 5 months) in the company and could not know all the processes that conformed a corporation as big as this one.

Sincerely, the situation was very difficult because the security staff was being born in the company and it was taking many responsibilities in order to close many breaches.

Some security policies existed and many others were being written. As I mentioned before, an Incident Handling procedure did not exist, however, the security staff counted with many tools that could identify, contain and recover from a possible attack.

Basically, each one of the persons that were in the security staff, had a laptop computer with dual boot (Linux & Microsoft Windows), a CD-ROM with secured and certified binaries, a Knoppix CD-ROM, a 4 Port Hub, straight-through and crossover cables and the access to a laboratory with a medium quantity of big computers where images of drives were stored, and where many times were done forensic analysis, applications test, penetration test, etc. The security staff counted with all these equipments at the moment in which happened the incident that I am relating.

Most of the tools used by the security team are open source tools and I will list each one of them below:

Binaries most used in Linux environment, but also developed for Windows

platform, were: ls, egrep, awk, find, strings, chmod, cut, dd, file, gzip, tar, date, time, uptime, md5sum, mv, nc, ps, pslist, diff, tail, cat, less, xargs.

Hexadecimal Editors: WinHex for Microsoft Windows and KhexEdit for Linux environment.

To do forensic analysis: Helix, Knoppix, The Sleuth Kit and Autopsy Forensic Browser.

Sniffers: Ethereal and tcpdump.

IDS': Snort.

Vulnerabilities Scanners: Nessus, Retina, LANGuard, Nikto and many of the tools included in Whoppix.

The main tool used in the analysis of this incident was khexedit, because a big part of the analysis was based in hexadecimal discoveries.

1.3.2. Identification

The identification phase was directly linked with a hexadecimal analysis of some files found. When I received the complaint and the advertisement about passwords usurpations I went to the physical location of the machine of one of the victim users, involved in the password usurpation. I found this computer on, because the user was using it to do his job. To try to maintain the machine in a similar state as was found and preventing the use of a possible comprise binarie I inserted a CD-ROM with most of the binaries used by Linux systems (ls, ps, chmod, etc.) but developed and ported to Windows plattaform⁷⁸.

I began to examine the performance of the machine (using the top command), the partitions of the disk (using fdisk command), and the files that were called when the machine started (examining the registry key HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run). Until this moment all the results appeared to be normal.

My next step was to examine the list of the process running, using for it the pslist command. A curious process called UpdateNT was shown in the process list (Figure 1), in a subsequent reproduction of the incident in a laboratory.

When I pressed Ctrl-Alt-Del to see the task manager, it was possible to show the description of an application mentioning “Update Windows SP1” (Figure 2). For this reason, I examined the folder Start Menu – Programs – Start Up and I found an application called Symantec.exe with a particular icon similar to the one used

⁷ <http://www.redhat.com/download/cygwin.html>

⁸ <http://users.erols.com/gmgarner/forensics/>

by default by Microsoft Visual Basic when a project is developed with it.

Due to all these discoveries and preventing to damage any part of the evidence I proceeded to do an image copy (using for it the dd command), sending all these bits through the network to store them in a file repository (using for this transmission netcat application). The procedure that was used generating and transmitting the image can be seen in the Figure 7 and Figure 8. I hid the IP address of the destination for terms of privacy.

Figure 8. Dd finished

With the image (an identical copy of the hard drive) in my laboratory I mounted it as read only mode in my Fedora box. I did a finding looking for any file called Symantec.exe, which was found in the path /Document and Settings/All Users/Menú Inicio/Programas/Inicio/Symantec.exe. In Windows, with an English version, the directory probably would have been /Document and Settings/All Users/Start Menu/Programs/Start Up/Symantec.exe.

I used the strings command to extract possible words that could allow me to

identify the file and its functionality and copied this information in an USB disk in a file called symantec.exe.str. An extract of these results can be seen in Figure 9.

I opened this file generated with cat (see Figure 9) command and some words as Form, VBA6.DLL, __vbaFreeVar, __vbaEnd, __vbaObjVar, __vbaLateMemCall, __vbaVarSetVar, C:\Archivos de programa\Microsoft Visual Studio\VB98\VB6.OLB, were found, and these words denoted applications generated in Microsoft Visual Basic.

Figure 9. Strings of Symantec.exe

However, in spite of this, I could see that the application was written using Microsoft Visual Basic but the case was not resolved, because it could be a proprietary application that the user used for any purpose. Although, with this discovery I discarded the possibility that Symantec.exe could be an application written by Symantec Corporation. For this reason I used khexedit application to analyze Symantec.exe; a view of the procedure that I followed is shown in Figure 10 and Figure 11.

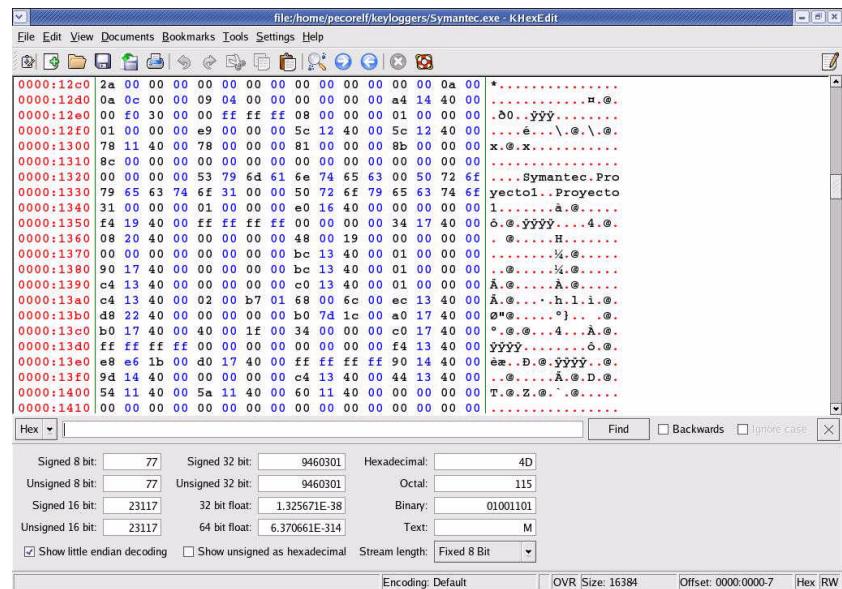

Figure 10. A view of Symantec.exe using khexedit

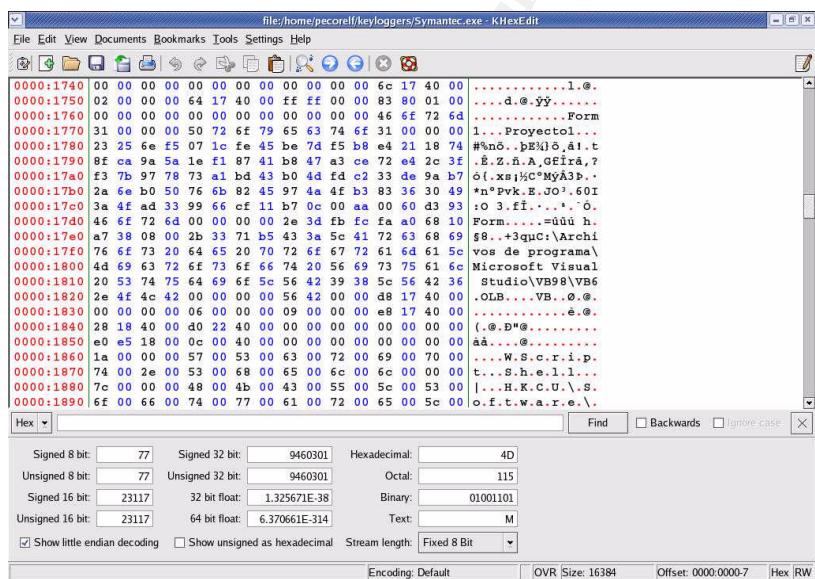

Figure 11. A view of Symantec.exe using khexedit (Continuation)

Continuing the examination of the entire file using khexedit, I found in sector 0x1900 a possible call to another application called UpdateNT.exe, that was not visible with strings, possibly located in c:\winnt\system32\, as is shown in Figure 12. This application UpdateNT.exe could be linked with the curious process that was running in the machine and that was shown in Figure 1.

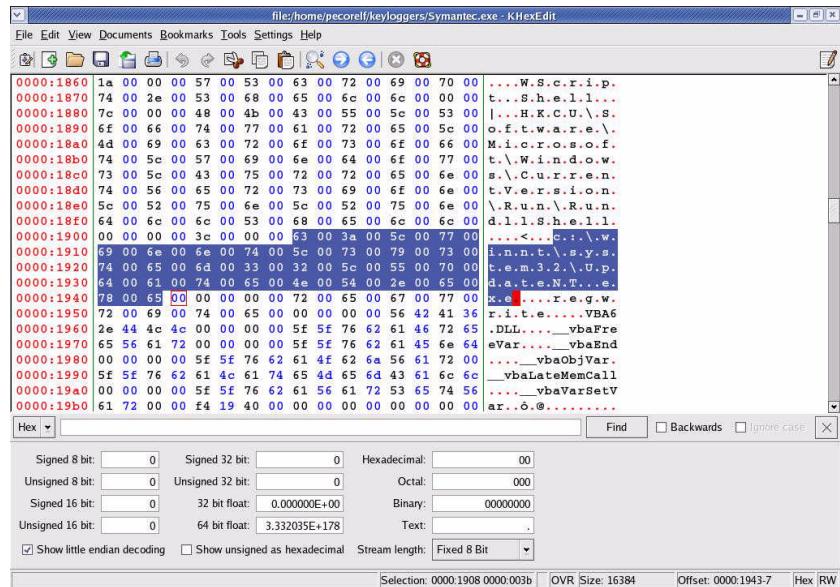

Figure 12. Path for UpdateNT.exe

In the mounted image, once again, looking for UpdateNT.exe, I found one file with this name located in ./winnt/system32/UpdateNT.exe. My next step was to generate a file with the result of applying the strings command over it, called updatent.exe.str. All these steps are shown in Figure 13.

```
[root@LinuxForensics img1]# find . -type f -name [uU]pdate[nN][tT].exe
./winnt/system32/UpdateNT.exe
[root@LinuxForensics img1]# strings ./winnt/system32/UpdateNT.exe > /mnt/usb/updatent.exe.str
[root@LinuxForensics img1]#
```

Figure 13. Finding the UpdateNT.exe and generation of its strings

Reviewing the file generated, I found similar words to be seen in symantec.exe.str denoting an application written using Microsoft Visual Basic. Again I used khexedit and opened this file to examine it inside. In sector 0x1558 I saw the name of the process that I had seen in the machine when I pressed Ctrl-Alt-Del in my first contact with the machine (see Figure 2 and Figure 1). This name was “Update Windows SP1”, and the first view of it is shown in Figure 14. In this way, this file is linked with the process mentioned.

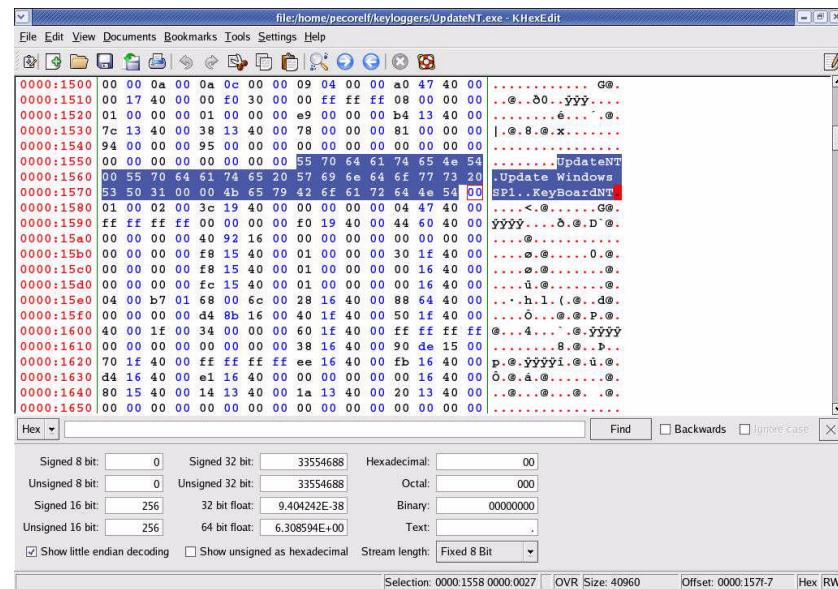

Figure 14. Opening UpdateNT.exe with khexedit

Also, as it is shown in Figure 15, in sector 0x22e0 the words “Fecha – Hora” (Fecha⁹ is Date in English and Hora¹⁰ is Time in English) called my attention, and before that, in sector 0x22c0, a file named archivo.txt that was located in c:\winnt\system32 (archivo¹¹ is the translation of “file” in Spanish) also called my attention.

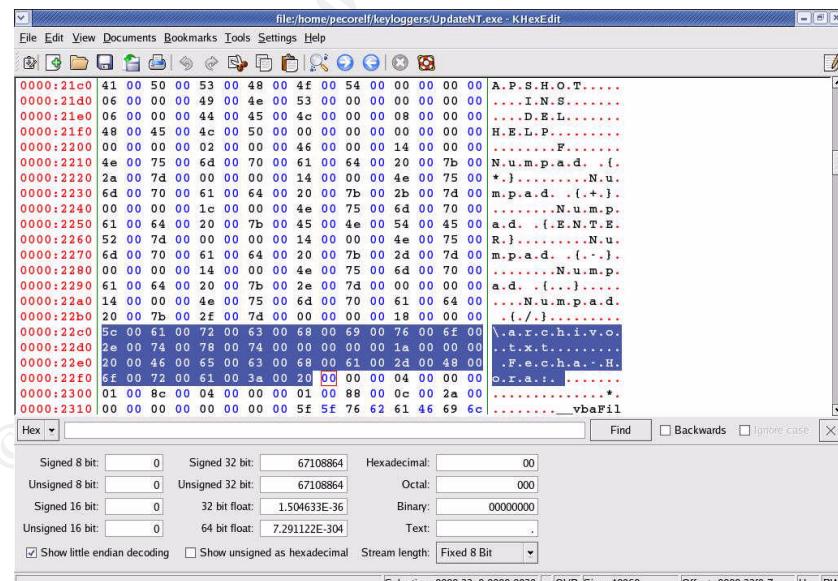

Figure 15. Words found with khexedit

⁹ <http://www.wordreference.com/es/en/translation.asp?spen=fecha&v=b>

¹⁰ <http://www.wordreference.com/es/en/translation.asp?spen=hora&v=b>

¹¹ <http://www.wordreference.com/es/en/translation.asp?spen=archivo&v=b>

I had not seen these words before, when I analyzed the strings generated for UpdateNT.exe. Because of it, I did a finding in the mounted image with the file called archivo.txt and I found it in the location c:\winnt\system32. I used the file command to determine its type and the result was a text file. These steps are shown in Figure 16.

```
[root@LinuxForensics img1]# find . -type f -name archivo.txt
./winnt/system32/archivo.txt
[root@LinuxForensics img1]# file ./winnt/system32/archivo.txt
./winnt/system32/archivo.txt: ISO-8859 English text, with very long lines, with CRLF line terminators
[root@LinuxForensics img1]#
```

Figure 16. Finding and identification of archivo.txt

I used a text editor to open this file and the surprise was that the content of it included many users' names, and passwords of the local user of the computer. An important discovery was that the logins of System_M and its associated password were stored in this file. It is important to note that the format of the users in System_M is an integer of five digits. In the Figure 17 we can see that the password of the user 10046 was ELIANA2LI. The dates shown in the figure that were stored by the application in the file are in format dd/mm/yyyy.

```

...
[REDACTED] Main Menu (v 4.1.0) Fecha-Hora: 4/6/2004 9:30:59 AM"
```

Figure 17. Content of archivo.txt

At that moment, I identified that Symantec.exe was an executable file that was invoked when the machine started up, because its the location was in Start Menu – Programs – Start Up. When Symantec.exe is executed, it does not open a windows or a signal of execution, but invisibly the application UpdateNT.exe located in /winnt/system32/ is executed.

UpdateNT.exe was a kind of keylogger that captured all the keys pressed by the keyboard, for recording in a file called archivo.txt. Although all the operating systems patches and the antivirus signatures were applied in these applications, they were not detected due to an internal development and were not published.

They only were used to capture a reduced quantity of information in few computers, that was used later to do fraud.

At this moment I had identified the way to extract and rub the passwords of System_M users. In the company the password policies were not always applied and many of the Administrator passwords in many computers were the same. With this password “universally known”, any user connected to the net could map any hard drive of any computer and check all the files using the folder sharing option of Windows systems. After many investigations, nobody used any machine more than the responsible user. For this reason I suppose that the installation of the software was done through the net.

Some weeks later it was committed other fraud using the password of one user. For this reason I went to the physical location of the machine and applied the same procedure described above (check the process running, get the image, etc.)

Based in the previous analysis I went directly to the folder /Document and Settings/All Users/Menú Inicio/Programas/Inicio/ and there I found a suspected file called twain.exe. I copy this file in a specific location and applied file command over twain.exe as is shown in Figure 18 and the result was an executable file.

```
[pecorelf@LinuxForensics keyloggers]$ file twain.exe
twain.exe: MS-DOS executable (EXE), OS/2 or MS Windows
[pecorelf@LinuxForensics keyloggers]$
```

Figure 18. Identification of twain.exe using file command

I also did a search by the name “archivo.txt” and no files were found. I opened twain.exe with khexedit and in a fast examination I discovered that the file was very similar to UpdateNT.exe. Therefore, I used diff to compare the strings generated over UpdateNT.exe and twain.exe and the results are shown in Figure 19 and in Figure 20.

```
[pecorelf@LinuxForensics keyloggers]$ strings twain.exe > twain.str
[pecorelf@LinuxForensics keyloggers]$ strings UpdateNT.exe > UpdateNT.str
[pecorelf@LinuxForensics keyloggers]$ diff twain.str UpdateNT.str | less
```

Figure 20. Diff between UpdateNT.exe and twain.exe

I opened twain.exe with khexedit in order to examine in detail this file and I noted some things that were very similar in comparison to UpdateNT.exe. For example, as it can be seen in Figure 21, twain.exe is an application also developed in Visual Basic; and in this moment I thought that probably some light changes had been made to avoid the antivirus.

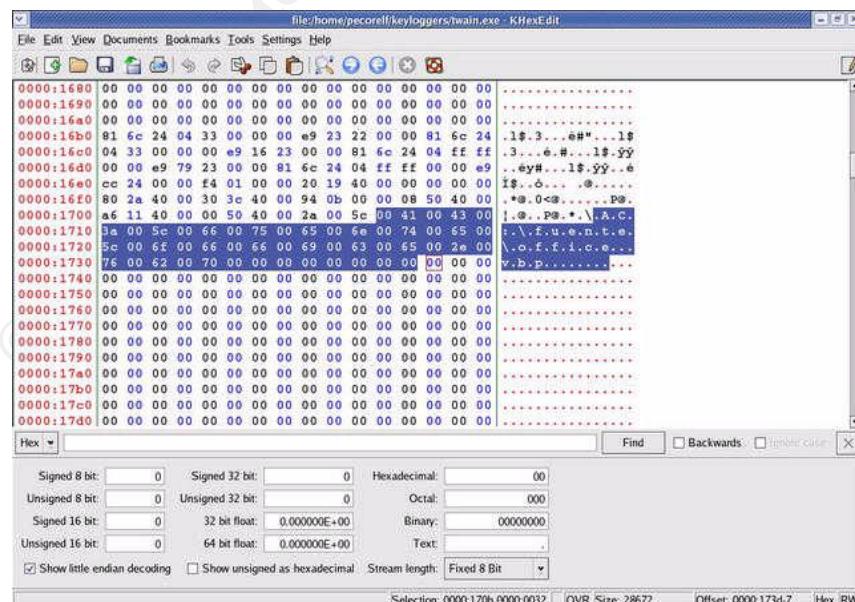

Figure 21. Path of possible source code developed in Microsoft Visual Basic

A very similar entry to the entries encountered in UpdateNT.exe was found in twain.exe, and it was the file where the data was stored. With twain.exe the data was stored in a file called “mail” without extension, as is shown in Figure 22. The tag “Fecha – Hora” was equal (remember Figure 15).

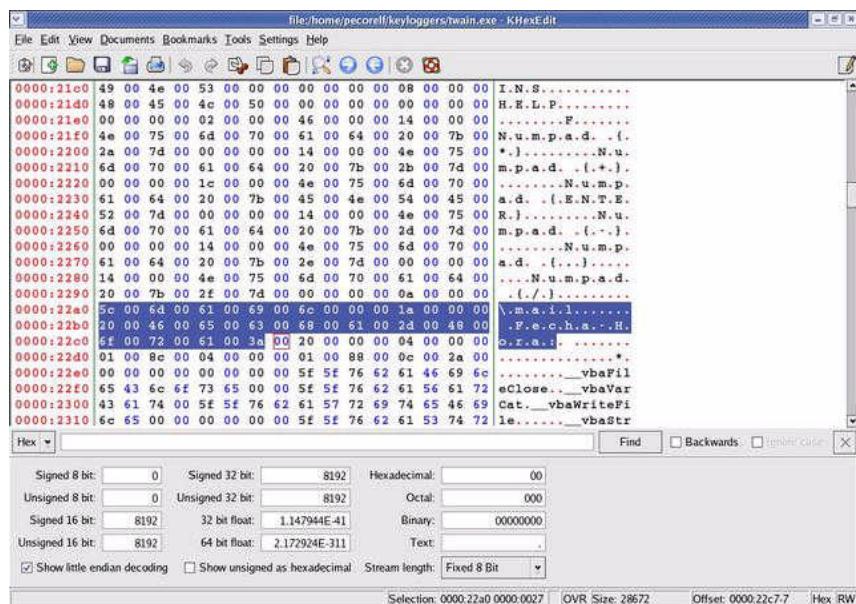

Figure 22. Presence of mail call and the tag Fecha - Hora

Another facts encountered during examination were the words that linked twain.exe with an application developed in Microsoft Visual Basic, as the path shown in Figure 23 and all the functions and name references in Figure 24.

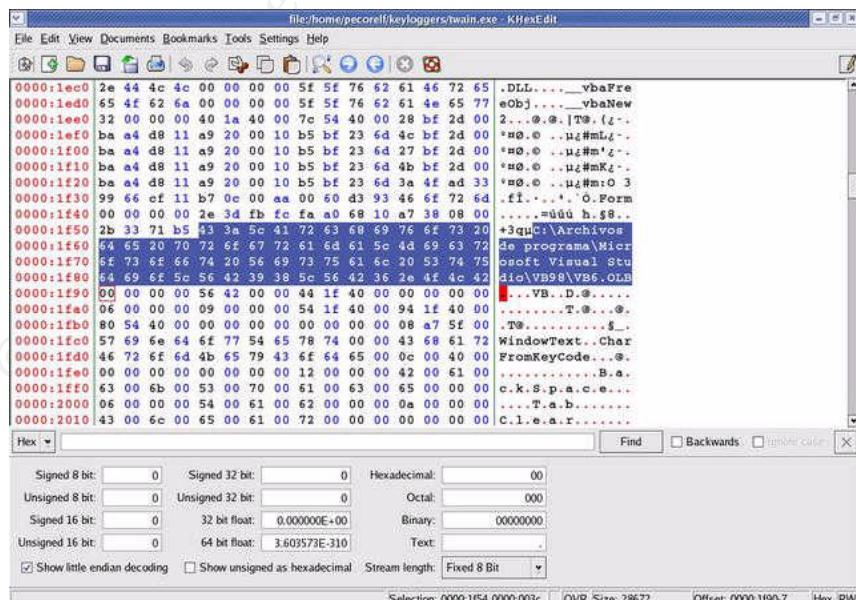

Figure 23. Installation's path of Visual Basic

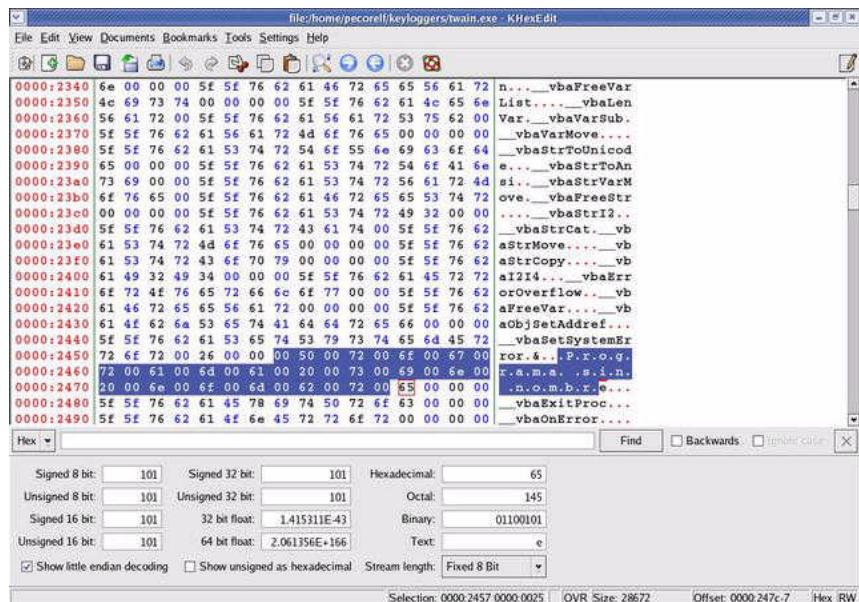

Figure 24. Call to Visual Basic's functions and the name of the project (Spanish)

I found over the image mounted by mail the name of the file and I found one of these located in c:\winnt\system32. I opened it with less command and the structure of the file was equal to the structure of archivo.txt. To view the mail file go to Figure 25.

```

Figure 25. Content of mail.txt

The structure of the mail file was equal to the file `archivo.txt`.

On this way, I could identify that once again someone had developed a very similar application to rob the passwords of the users. Fortunately, from the time of the first incident, some plans had been applied, and thanks to it the consequences were not major.

Nowadays, with the changes applied in System_M and in all the plattaform, there has not been detected any other fraud against System_M. For these reasons I consider that the identification phase was a total success because actions to discover the source of the problem were taken fast.

An important phase during the identification phase was how to catch the culprits, as I explained in section 1.2.2, as I had installed the Ethereal sniffer, I still checked to get the capture done, also searching by the destination IP address, setting the IP address of the machine of the user where I found the keylogger twain.exe. The result was a lot of number of packets; however, I reviewed each packet and I found a connection from IP x.y.54.41 which was transferring a file called twain.exe to the computer of the affected user (x.y.54.83). The possible attacker was located in the same commercial office and therefore in the same subnet.

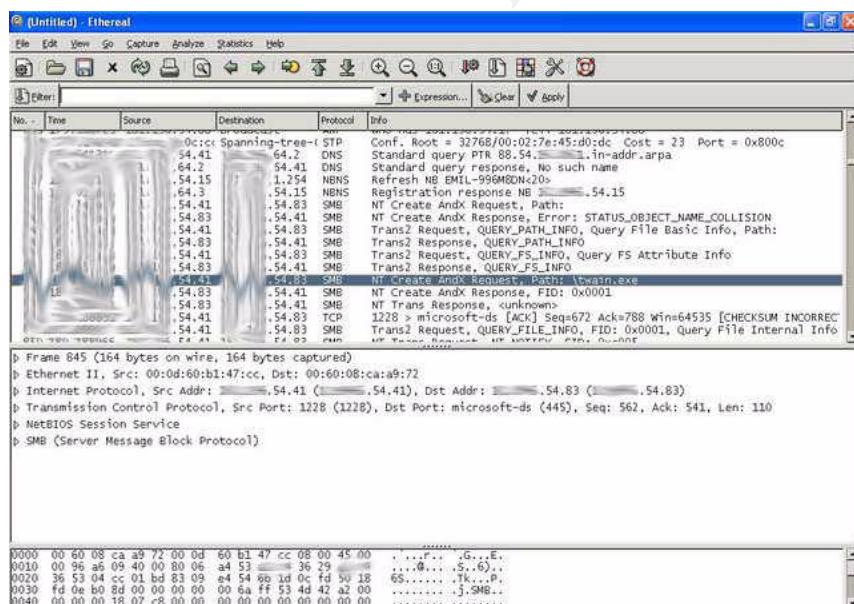

Figure 26. twain.exe found in the ethereal capture

Using the option “Follow TCP Stream”¹² of Ethereal I could rebuild all the transfer of the file and I copied it in a new file called twain.temp as is shown in Figure 27.

¹² <http://www.ethereal.com/docs/user-guide/ChAdvFollowTCPSection.html>

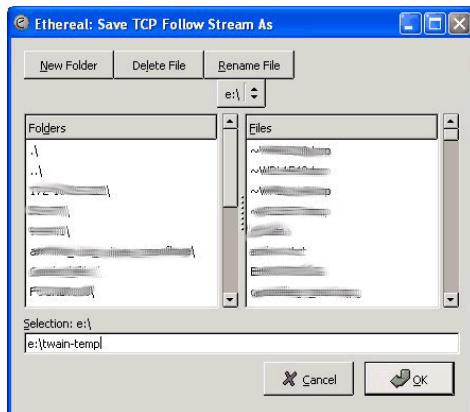

Figure 27. Saving twain-temp

In the Ethereal capture I discovered that the length of the file `twain.exe` was 28672 bytes as is shown in Figure 28.

```
microsoft-ds > 1228 [ACK] Seq=1284 Ack=30034 Win=17552
Write AndX Response, FID: 0x0001, 28672 bytes
Trans2 Request, SET_FILE_INFO, FID: 0x0001
Trans2 Response, SET_FILE_INFO
```

Figure 28. Size of transfer of `twain.exe`

I opened `twain.temp` with khexedit and did a hexadecimal search looking for the hex value `4D5A9000`, that is, the header's beginning of any executable file. In sector `0x09fe` I found this value, that it is equal to the one in sector `0x09fe` that began the executable as is shown in Figure 29. For this reason, from this position (`0x09fe`) in the file I moved the cursor to the next 28762 bytes (Figure 30) and copied this portion in a new file that I called `twain2.exe` (Figure 31 and Figure 32).

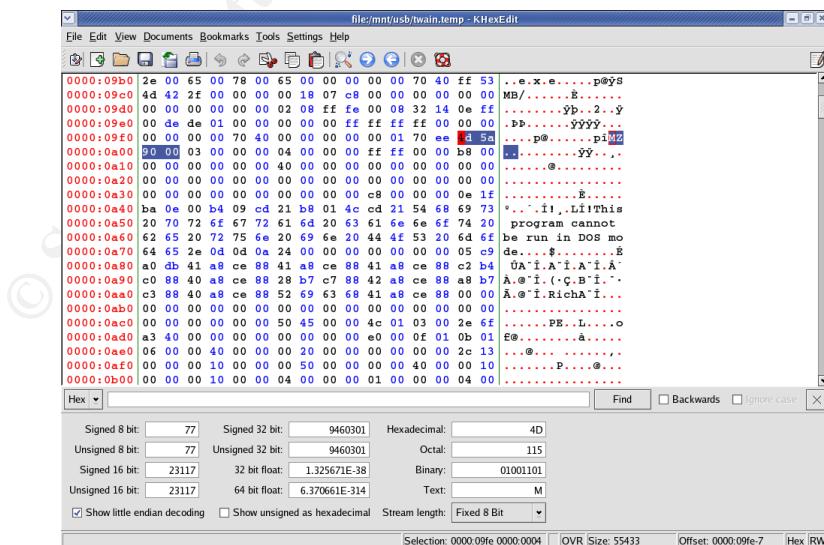

Figure 29. Header of executable file found in the transfer

Figure 30. Offsetting 28672 from 0x09fe

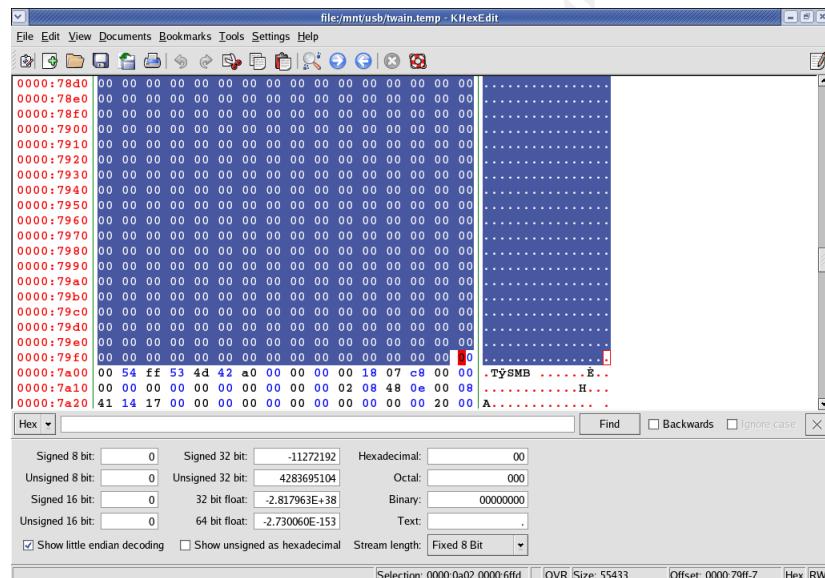

Figure 31. Extracting twain.exe from the transfer

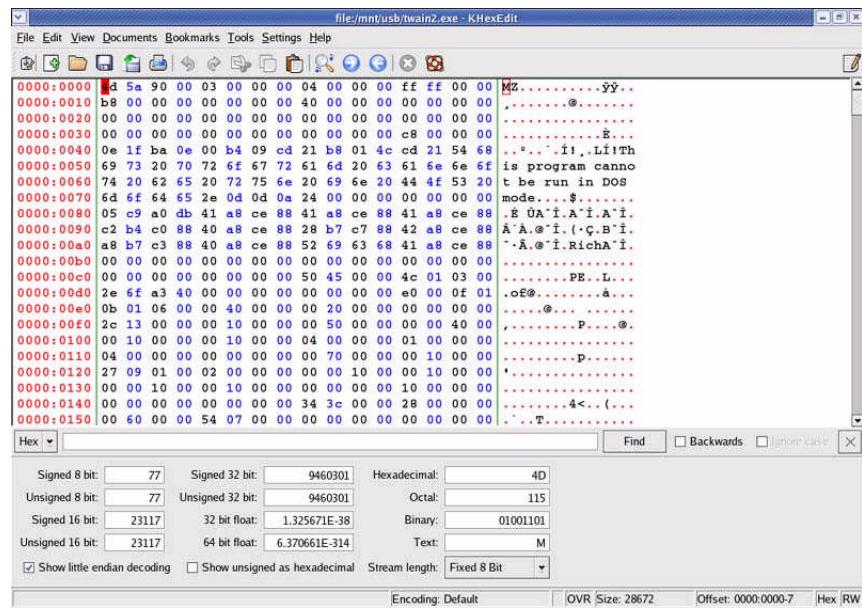

Figure 32. twain2.exe generated

I calculated the MD5 value for this captured file and the MD5 value for the file encountered in the image, and the values were equal, as is shown in Figure 33 (MD5 value 60d679282fe172b5aa9ea8dd952b6412), thus demonstrating that the file found in the image was equal to the one transferred to the net by the attacker.

```
[pecorelf@LinuxForensics keyloggers]$ md5sum twain.exe
60d679282fe172b5aa9ea8dd952b6412  twain.exe
```

Figure 33. MD5 value of twain.exe

Additionally, with the capture done by Ethereal, I found the source IP where was done the connection to transfer the file. Looking for the logs of the DHCP server I could localize the machine and his owner and responsible of this, which was located in the same commercial office.

I confiscated the machine and the legal department of the company called the user in order to ask a group of questions related with the case. The user admitted his culpability and said that the confiscated machine was only used to transfer the keylogger. The legal department made the procedures to do an unlawful entry in the house of the employer.

1.3.3. Containment

The containment phase entered in action when the security staff was contacted with the information of some password usurpation. Some security staff members were dispatched to the physical location to investigate the fact. As I have explained, shortly before the following actions were taken:

- All the binaries used to identify process running, open applications, network status and in general the status of the system were trust binaries stored in a CD-ROM that each one of the security members has with it.
- It was added an Access Control List in the perimetral firewall to avoid that possible information could be sent through Internet.
- It was generated an image of the disk, using dd which was sent by the network to a server disposed to this end.
- During all the investigation, more than two machines were analyzed, where there were running clients of System_M. Each one of them had similar characteristics; however, each one were identified with a tag in order to follow up some data in the future, if it could be required. I did a specific format of tags with the fields shown in Table 1.

Field	Description of the field
Evidence #	Contained a numeric ID of the computer collected. This ID began in the number SM-1, where SM was a fixed value and the number was incrementing.
User name	Contained the first and last name of the user or users responsible for the machine.
Localization	Contained the specific place where was located the machine, could be a commercial office in a shopping center, a computer of an administrator, etc.
Model	Contained the main features of the machine, processor, hard drive, etc.
Serial	Contained the serial number of the case, printed generally in a side of the box.
Investigator	Contained the first and last name of the investigator that seized the machine.
Date & Time	Contained the date and time when the machine was seized.

Table 1. Tag's description used in collecting the analyzed systems

The machines seized during all the investigation process were tagged with the information shown in Table 1; in order to protect the confidentiality of the company, the tags that I will show below with the collected information were lightly modified in some fields as User name and Localization (where I will use names like Place_1, Place_2, etc.)

Evidence #	SM_1
User name	User_IS (changed by confidentiality)
Localization	Place_1 (changed by confidentiality)

Model	HP Vectra VE. Pentium III 550MHz. DD 4GB. 128MB RAM.
Serial	MX94160548
Investigator	Francisco Pecorella
Date & Time	Jun 25, 2004 – 11:00

Table 2. Tag identifying the first machine analyzed

Evidence #	SM_2
User name	User_FR (changed by confidentiality)
Localization	Place_2 (changed by confidentiality)
Model	Dell Optiplex GX1. Pentium III 450Mhz. DD 2GB 64MB RAM.
Serial	2PG911
Investigator	Francisco Pecorella
Date & Time	Aug 27, 2004 – 07:30

Table 3. Tag identifying the second machine analyzed

- The computer was powered off, and the hard disk was identified with tape as involved in a security incident and was placed in a secure location with secure access and a form of access and chain of the custody where the name, date and time and finality of each access are filed.
- These steps were reported to the security manager and all the steps taken in a text file were registered to do at the end of the investigation a complete report.

1.3.4. Eradication

The eradication phase was the simplest of the six phases; in this case, the organization used Tivoli in all the computers for monitoring, resources statistics and remote installations. Additionally, all the computers used McAfee Personal Antivirus and the updates were always activated.

Also, the organization used ClamAV as antivirus software to analyze all the mails of the employees and aliases that uses the company for different purposes.

With all these spread resources, a patch was the most advisable solution to eradicate the malware applications. For this reason, once detected the keyloggers, as I mentioned before, we sent some samples of them to the major antivirus companies that were used by the company, in other words, McAfee and ClamAV.

Most of the antivirus companies sent to us the update sign, and using Tivoli we distributed this file to all the computers of the network. This process was repeated five times, in order to cover all the computers that in a first phase could be off or simply offline for any reason.

All the ClamAV servers update its definition virus each four hours automatically, however when it was received the answer of ClamAV recognizing the keylogger, it was forced an update to avoid that the software could be distributed by e-mail.

With all these steps that were conducted in less than half a day, we could be sure that the application was removed effectively. When it was detected the second keylogger, the steps that were taken were equal to the first occasion. We sent the binarie sample, received the updated sign and we spreaded it by the network using Tivoli in repeated times.

Later, we did not see any signal of these applications installed in any computer.

1.3.5. Recovery

The recovery phase that was conducted by a security team, joined with other functionals areas of the company, was not a hard phase because the damage could be mitigated with a procedure that forced all the users to change its passwords immediately and for a period of two weeks these password expired each two days. In this way, if any computer would have had the keyloggers installed, these two weeks were enough time to remove them.

Once the signatures of the anti-virus to remove the malware applications were distributed, it was run a process that did a finding in :/winnt/system32, removing the file archivo.txt or the file mail, to avoid that any bad intended user could extract the last passwords stored by the applications.

To ensure that these application were effectively removed from the systems, some computers of persons, which were using his/her credential, were chosen at random, and the security team examined his/her computers to test if the patch run removed correctly the malware, which resulted in a success.

Unfortunately, the recovery phase could not recover all the lost money that these applications originated, but with the measures taken, sniffing the network, as was explained in section 1.3.2, could catch the attackers group.

1.3.6. Lessons Learned

With the incidents occurred, the security team of the company highly enforced the credentials and security policies that existed in the systems of the organization.

When the installation of the malware code was committed, most of the final users'

machines had a default password as Administrator. With this default password anyone could do login in any machine and install, execute or simply rub sensitive information. The policies related to these passwords was changed, establishing a project that we called “Perfiles” (perfiles is the translation of profiles in Spanish). This project included a series of changes made over the permissions that each user in the domain had over the machines. In this way, the administrators’ passwords are different to those of any user and they can do login as administrator machine only in the computer that they have been assigned.

In spite of these security policies applications, existed the possibility that many passwords could be weak¹³ passwords. As all the users use authentication against an Active Directory, all the passwords are stored in a common file, called sam (Security Account Manager), that is located in %SystemRoot%\repair\|. This file could be copied using pwdump¹⁴ (pwdump is an application to retrieve passwords hashes locally or remotely from a Windows NT/2000/XP system).

With all the password hashes copied in a file, the company acquired the software LC5¹⁵ (LC5, is the most recent version of L0pthCrack and is a software used to crack passwords with a hash as input), and we installed this application in a machine with four processors of 3.0 GHz, specifically a Dell equipment PowerEdge 6650¹⁶.

We programmed a task that once each two weeks copy all the hashes passwords in a file, using pwdump and this file is used as input to LC5 to crack the passwords, using for it a lot of dictionaries files and precomputed hashes. With the output of the LC5 are identified the weak passwords in order to inform to the user this condition and recommend a change of it following our passwords policies. Additionally, each password expires in sixty (60) days, and it forces a change of it. The new password can not be any of the previous 10 passwords

With these policies we are trying to assure that all the users have strong passwords and that these passwords, used as credentials to enter to the domain and to the computers are not a default and trivial phrase.

The main purpose of the installed keyloggers, was to rob the credentials (ID and password) of the user in System_M, and in this way be able to impersonate this person and commit fraudulent deeds. Because of the importance of System_M, it was implemented and developed an authentication system, more robust and difficult to break, using tokens RSA¹⁷. These SecureIDs allow that only the person that has the key generator could access the system with his/her credentials, much better, these keys are changing periodically at a short time.

An important lesson that the whole company learned is that nobody can trust nobody. In this case, the attacker was inside the company, and was workpartner and friend of many of the users that were victims of credential usurpations. Nowadays, many of the users save his/her passwords with extreme careful.

The company has almost 10000 employees. Approximately four months ago, in sessions of twenty persons daily, the employees are receiving lectures about security policies and ways to prevent the usurpation of credentials and other types of attacks. In these lectures, trained personal explains the use of antivirus applications, personals firewalls, etc. At the end of these lectures, all the participants sign a comprise called “Código de Conducta Empresarial” that specify and oblige the persons who sign it to protect his/her credentials and apply and carry out all the security policies. In the case that any of these policies could not be fulfilled, and this fact comprises the security of the company or any part of it, the employee will be the direct responsible, assuming all the consequences of it.

All those measures give the company more security and prevent future similar security incidents, for oversight, or not fulfilling the application of security policies.

1.3.7. Exploit/Attack/Vulnerability References

An important phase, when an attacker has gained access to a target, is to try to maintain this access to enter and leave the system when he desires. In this phase, commonly called “maintaining access”, we have to use applications as trojans, backdoors and rootkit. In the incident that I handled, the attacker had access to the system due to the weak and trivial administrator password; with this password the attacker and many other users could enter into the victims’ computers with high privileges, to install new applications, to add new files, or simply to rob any data.

There exist many differences between trojans, backdoors and rootkits, and equally different kinds of them. A very complete chapter about these topics can be read in Ed Skoudis. Counter Hack. New Jersey: Prentice Hall, 2001, where are covered all the differences between the concept of each one and it is explained in detail the functionality of them.

Other book that could be interesting to learn about Malware Analysis is the Chapter 11 of Ed Skoudis & Lenny Zeltser. Malware: Fighting Malicious Code. New Jersey: Prentice Hall, 2003.
