Global Information Assurance Certification Paper

GREM Practical
(GIAC Reverse Engineering Malware)

Sven Olensky

SANS Online Course 2004
Practical Version 1.0

Contents

1. Preface

This is my submission to fulfill the requirements for the practical assignment part of the GREM / Reverse Engineering Malware. It consists of a detailed analysis of an unknown, possibly malicious binary.

Thanks to my wife Jamie and our kids (Neo and Kiki [DOGS]) for loving me like they do.

Sven Olensky
August/September 2004

2. Introduction

This paper consists of 7 sections plus an appendix.

2.1. Legend

- commands that are getting executed, comments and the output of these commands in the assignments are typed in Courier New
- words in brackets [WORD] indicates a reference that can be found in the appendix
- '$' in front of the command means user-level access, '#' means root-level access
- '//' means comment

Examples

```
$ ls –l
// list contents in long form, user-level access

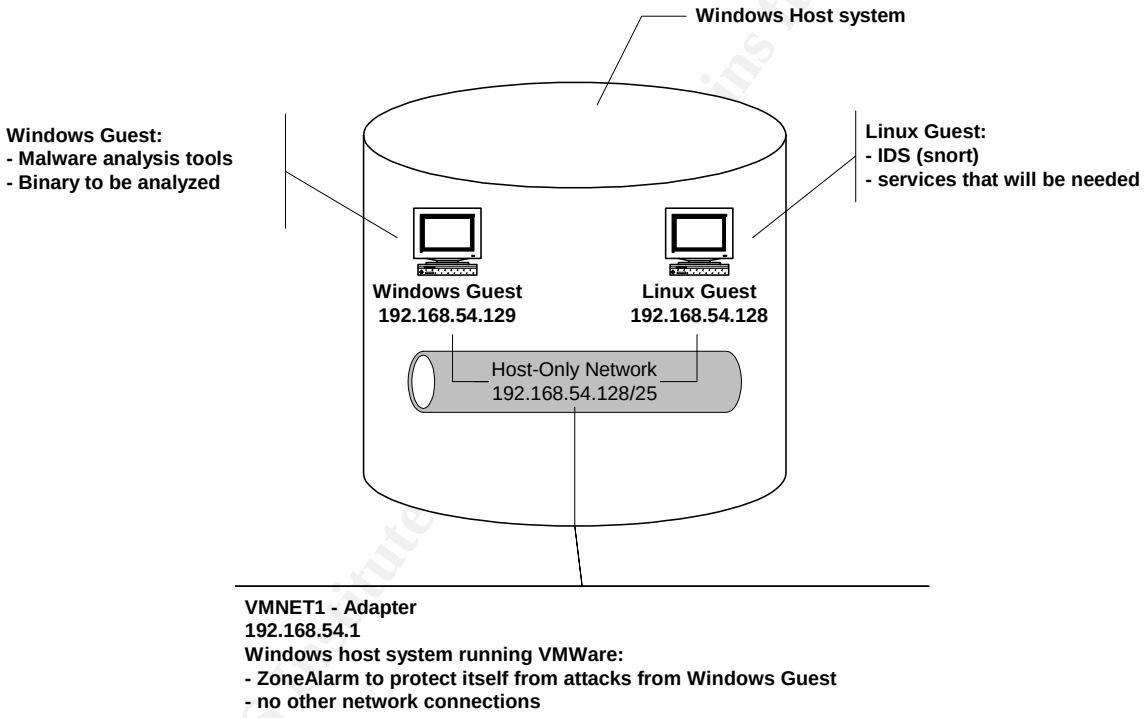
# rm –rf *
// delete everything, starting in this directory, as root
```

3. Laboratory Setup

Laboratory Setup - 10 points

Describe in detail your laboratory setup. We suggest using the setup described in the course material, or you may use your own set up as long as it meets the reverse-engineering needs of this practical assignment. Describe the hardware, networking, and software resources you used for your analysis. Explain laboratory isolation precautions that you implemented to protect your production environment from infection. Make sure to include a detailed description of each resource, its purpose, how, and where how you used it during the analysis.

3.1. Lab setup



The lab is based on a VMware- setup. The host system running VMware is a laptop running Windows 2000 Professional with all the latest security patches. The guest operating systems that are installed within the VMware environment are one RedHat Linux system and one Windows 2000 Professional system. The RedHat Linux system will run the Intrusion Detection System Snort and emulate any services that might be requested by the Guest- Windows 2000 System, on which the malware analysis will take place and on which the actual malicious application will be executed.

The network that is shared between the guests and the host system is a VMware host-only network which is only accessible by those systems. It is closed off to the outside. In addition to that, the laptop's real network connection is unplugged to protect the surrounding networks in case the trojan finds its way out of the protected VMware environment.

3.2. Tools used

The Windows 2000 guest system has the following tools installed that will aid in the analysis of the malicious executable:

- IDA Pro disassembler [IDAPRO]
- OllyDbg debugger [OLLYDBG]
- Various SysInternals tools: RegMon (monitoring of registry), FileMon (monitoring of file accesses), TDIMon (monitoring of network access), ProcExp to show active processes [SYSINTERNALS]
- BinText to analyse string contents of files [BINTEXT]
- RegShot to compare registry snapshots [REGSHOT]
- WinZip to unpack any required archives [WINZIP]
- PEInfo to analyse file type and other file details [SANSCLASS]
- file for file type analysis [FILE]

The laptop (the host system that is running VMware) is also running Zonelabs ZoneAlarm to protect itself from any potential malicious traffic that could be initiated by the binary.

4. Properties of the Malware Specimen

Properties of the Malware Specimen - 5 points

List the following properties of the malware. Make sure to include a detailed explanation of your steps, and an interpretation of your findings.

- Type of file (e.g. executable, compressed, data, etc.)
- Size of the file
- MD5 hash of the file
- Operating system(s) it runs on
- Strings embedded into it

4.1. Type of file

This seems to be an executable, either MS-DOS or Windows.

4.2. Size of file

PEInfo states 41984 Bytes, 41.0 KB.

```
Path: C:\download\sanspractical\msrll.exe
     File size:   41984
    Image size:   1179648
File Alignment:   512
Resources account for 0.00% of the executable
41.0 KB (41,984 bytes)
```

4.3. MD5 hashes of the file

```
C:\download\sanspractical>md5sum msrll.zip
696c78651244b1ad0363a400a23d48ef *msrll.zip

C:\download\sanspractical>md5sum msrll.exe
84acfe96a98590813413122c12c11aaa *msrll.exe
```

4.4. Operating Systems it runs on

The string `'!This program cannot be run in DOS mode.'` below indicates that this is a Windows executable. The file tool is more precise:

```
C:\Program Files\GnuWin32\bin>file c:\download\sanspractical\msrll.exe
c:\download\sanspractical\msrll.exe: MS Windows PE Intel 80386 GUI executable no
t relocatable
```

This seems to be a MS-Windows executable for Intel-386-based systems.

4.5. Strings embedded in the binary

From PEInfo:

```
File pos   Mem pos      ID   Text
========   =======      ==   ====

0000004D   0040004D      0   !This program cannot be run in DOS mode.

```

Aside from Windows function calls in the last part of the string output, no useful information can be extracted from the character strings. It appears to be that the file is somehow packed or encrypted. The first lines indicate the section names.

```
00000178   00400178      0   .text
000001A0   004001A0      0   .data
000001F0   004001F0      0   .idata
00000218   00400218      0   .aspack
00000240   00400240      0   .adata
```

`.aspack` indicates that the file was packed using ASPack [ASPACK]

5. Behavioural Analysis

Behavioural Analysis - 35 points

Use your laboratory setup to perform a behavioural analysis of the unknown malware specimen infecting a system in the laboratory, with the malicious program under controlled conditions. Describe the analysis in detail. Describe your actions and your use of your the analysis tools in detail. Explain the implications of the behaviour of the malware specimen.

Example procedures:

- Monitoring file system access
- Monitoring registry / configuration access
- Monitoring / redirecting network connections
- Monitoring processes on the system

5.1. Preparations

Before the binary gets executed, all the monitors have to be in place and started:

- RegMon (monitoring of registry)
- FileMon (monitoring of file accesses)
- TDIMon (monitoring of network access)
- RegShot: take a snapshot of the registry before the binary gets executed so that the registry modifications can be seen later on
- ProcExp to monitor running processes

This section is split into two parts: the behaviour of the binary on the local machine and the behaviour of the machine on the network.

5.2. Behaviour of the Binary on the local machine

5.2.1. RegShot

Lets look at the comparison of the registry snapshots before and after the execution of msrll.exe, created by RegShot:

```

5.2.2. FileMon

Lets look at what FileMon logged during the execution of the binary. Only the interesting parts of the log file are listed.

These are the files that were read by the binary:

```
167     4:01:12 PM     msrll.exe:788  READ    C:\download\sanspractical\msrll.exe   SUCCESS
        Offset: 35328 Length: 2048

294     4:01:12 PM     msrll.exe:788  READ    C:\WINNT\System32\shell32.dll SUCCESS Offset:
0 Length: 12

408     4:01:12 PM     msrll.exe:1032 READ    C:\WINNT\system32\mfm\msrll.exe       SUCCESS
        Offset: 37376 Length: 4608

736     4:01:27 PM     msrll.exe:1032 READ    C:\WINNT\system32\msafd.dll   SUCCESS Offset:
0 Length: 32768

747     4:01:27 PM     msrll.exe:1032 READ    C:\WINNT\System32\wshtcpip.dll        SUCCESS
        Offset: 0 Length: 20480

854     4:01:28 PM     msrll.exe:1032 READ    C:\Documents and
Settings\Administrator\Local Settings\History\History.IE5\index.dat SUCCESS Offset: 4096
Length: 12288

981     4:01:28 PM     msrll.exe:1032 READ    C:\autoexec.bat        SUCCESS Offset: 0
Length: 0

1993    4:01:48 PM     msrll.exe:1032 READ    C:\WINNT\system32\rsabase.dll SUCCESS Offset:
0 Length: 32768
```

These are the files that were created by the binary:

```
168     4:01:12 PM     msrll.exe:788  CREATE  C:\WINNT\system32\mfm  SUCCESS Options:
Create Directory  Access: All
245     4:01:12 PM     msrll.exe:788  CREATE  C:\WINNT\system32\mfm\msrll.exe       SUCCESS
        Options: OverwriteIf Sequential  Access: All
521     4:01:12 PM     msrll.exe:1032 CREATE  C:\WINNT\system32\mfm  NAME COLLISION

```

These are the files that were written to by the binary:

```
245     4:01:12 PM     msrll.exe:788  CREATE  C:\WINNT\system32\mfm\msrll.exe       SUCCESS
        Options: OverwriteIf Sequential  Access: All
248     4:01:12 PM     msrll.exe:788  WRITE   C:\WINNT\system32\mfm\msrll.exe       SUCCESS
        Offset: 0 Length: 41984
1984    4:01:48 PM     msrll.exe:1032 CREATE  C:\WINNT\system32\mfm\jtram.conf      SUCCESS
        Options: OverwriteIf  Access: All
```

5.2.3. TDIMon

Looking at the TDIMon output, the following ports are being opened on the local machine:

```
7  47.29260898  msrll.exe:1032  811E2E88  IRP_MJ_CREATE  TCP:0.0.0.0:2200  Address Open

122  68.64820976  msrll.exe:1032  81316A88  IRP_MJ_CREATE  TCP:0.0.0.0:113  Address Open
```

The TCP ports 113 and 2200 are opened and listening for incoming connections.

5.2.4. Summary

The following changes stand out:

- a directory gets created, `C:\WINNT\system32\mfm`
- the binary gets copied over into the newly created directory
- the binary is identical with the original EXE file, as md5sum proves:

original file:

```
C:\download\sanspractical>md5sum msrll.zip
696c78651244b1ad0363a400a23d48ef *msrll.zip

C:\download\sanspractical>md5sum msrll.exe
84acfe96a98590813413122c12c11aaa *msrll.exe
```

created file in `C:\WINNT\system32\mfm:`

MD5 hashes match for the EXE files.

- a system service gets added, “RLL enhanced drive”, which loads up the binary automatically at each system boot, from its new location
- a configuration file gets created, “jtram.conf” in the directory `C:\WINNT\system32\mfm`
- the old binary gets deleted
- 2 ports are opened up on the local machine itself, TCP 113 and TCP 2200

Something else stands out when inspecting the FileMon output: msrll.exe queries the file index.dat [INDEXDAT] in the Temporary Internet Files-Folder of the Administrator:

```
23381   6:31:16 PM     msrll.exe:1108 QUERY INFORMATION     C:\Documents and
Settings\Administrator\Local Settings\Temporary Internet Files\Content.IE5\index.dat

        SUCCESS Length: 212992
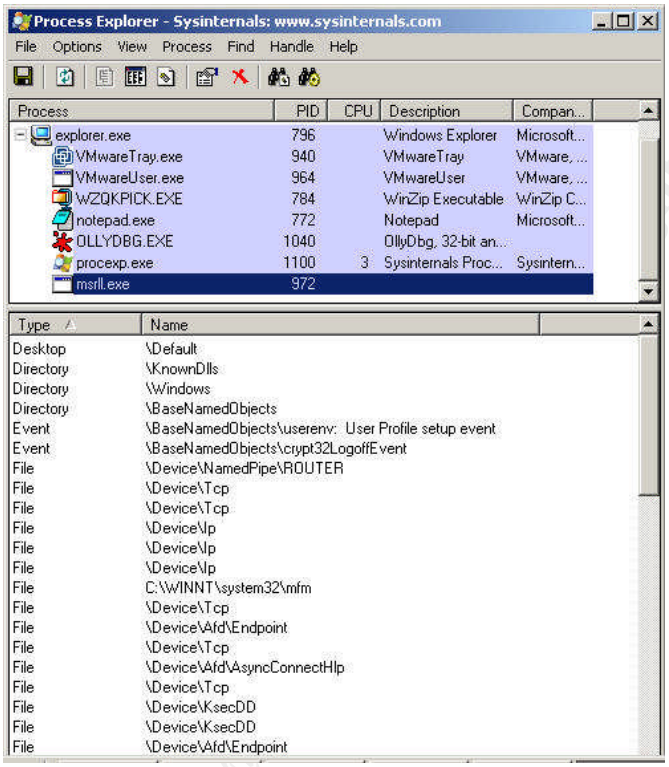
```

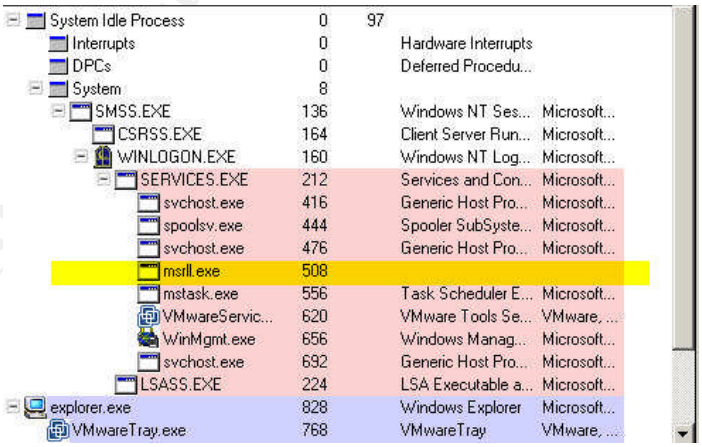
This seems to happen about every 30 seconds while the binary is running.

5.2.5. Processes

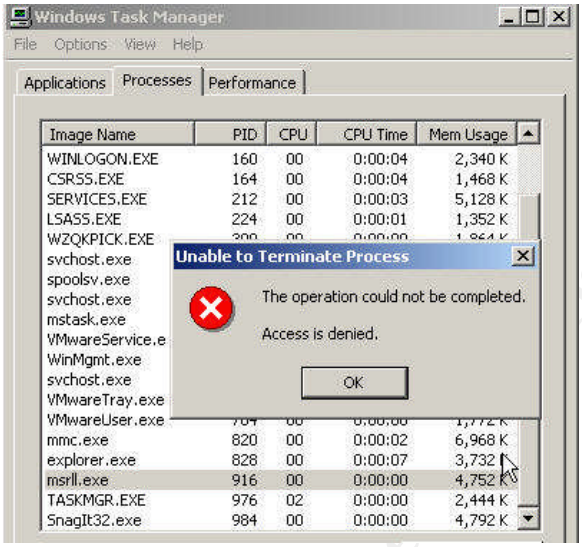
Whether the binary is executed by itself or within OllyDbg, the process ‘msrll.exe’ shows up in the process list.



Once it has installed itself as a system service and the system has been rebooted, it shows up in the list of running services:



The ‘service’ can be killed using the process explorer, but not by using the standard Windows Taskmanager.



At any rate, hiding the process would have increased the stealthiness. Maybe the supplied specimen was less advanced then later versions that actually would hide the process, or it was desired by the author to show the process as running.

5.2.6. jtram.conf

Lets look at the string contents of jtram.conf, the file that gets created when msrll.exe is executed for the first time.

```
File pos   Mem pos      ID   Text
========   =======      ==   ====
00000000   00000000      0   YwERACWWtLmMJ1BGq7OafIjzfhtrOxAnI/gkYkxNEDKmYu6qYA==

pP8jALz70I4nSAWuDJdC2JWCO65p+ykra6EvhDayFN4MNweHPVEGuz842Dx+V7Sy5HS9FgJ1tA==
```

The content looks encrypted. That might explain why msrll.exe made use of the RSABASE.DLL, the encryption library.

5.3. Behaviour of the Binary on the network

As mentioned in the lab setup section, the Windows virtual machine that is executing the binary, the Linux host and the VMWare host system share one host-only private network that is separated from everything else. The Linux machine is running snort to monitor the network traffic that is being generated by the infected Windows system.

For clarification:

- 192.168.58.129 is the Windows guest system executing the malicious binary
- 192.168.58.128 is the Linux guest system running snort and other services we may run
- 192.168.58.1 is the VMWare host system

5.3.1. First network trace

The infected Windows machine tries to do a DNS lookup for collective7.zxy0.com, using its gateway (the VMWare host system) as DNS server. Of course, no DNS service is running on that machine, so the DNS query fails.

5.3.2. Fixing DNS

In order to see what the infected system does when DNS succeeds, we will need to make sure that it assumes that collective7.zxy0.com resolves to a reachable, yet secure, host. Hence we will add a hosts entry on the infected system to point collective7.zxy0.com to 192.168.58.128, the Linux guest system that resides in the same protected network.

Steps to undertake:

- terminate the msrll.exe process
- modify the hosts file
- restart the msrll.exe process
- monitor the network

5.3.2.1. Modifying the hosts file

The hosts file resides in C:\WINNT\system32\drivers\etc. It will be modified to look like this:

```
[…]
# Additionally, comments (such as these) may be inserted on individual
# lines or following the machine name denoted by a '#' symbol.
#
# For example:
#
#      102.54.94.97     rhino.acme.com          # source server
#       38.25.63.10     x.acme.com              # x client host

127.0.0.1       localhost
192.168.58.128  collective7.zxy0.com

[…]
```

5.3.2.2. Testing the changes

After restarting the msrll.exe from C:\WINNT\system32\mfm (since the original binary was deleted when it was first executed), the network traces show the following:

```

```

msrll.exe obviously accepts ‘our’ IP for collective7.zxy0.com and tries to connect to the ports 6667, 9999 and 8080 on the machine. No services are running on those ports of course, so we will start netcat in listen mode to listen on those ports, in order to see what kind of data is transmitted.

5.3.2.3. Running Netcat

We will start netcat (nc) as following, each one in a separate console on the Linux system:

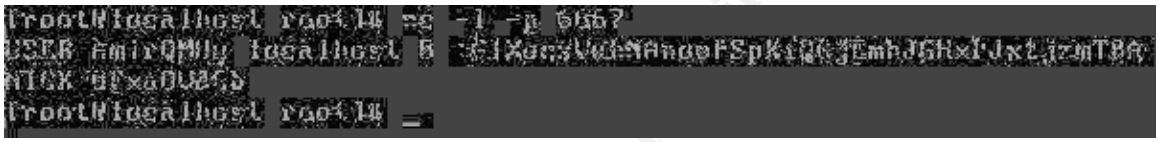
Console 2:
nc –l –p 6667

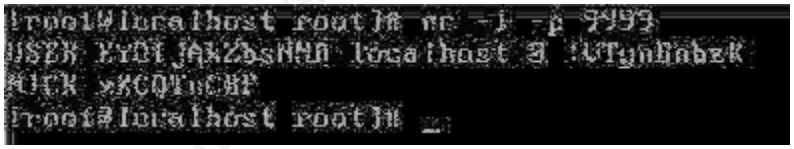
Console 3:
nc –l –p 8080

Console 4:
nc –l –p 9999

We now restart msrll.exe and see what data will be transmitted when connected to those ports.

The consoles show the following:





This is a typical IRC server connection attempt. Msrll.exe tries to connect to external IRC servers.

To see whether this assumption is true or not, we will start an IRC daemon on port 6667. At the same time, the binary will be monitored to see if it still tries to establish connections to the other ports above, 8080 and 9999. We achieve this by letting nc listen on those ports.

IRC server running on port 6667, netcat listening on ports 8080 and 9999

After msrll.exe was restarted, we see different traffic patterns:

```

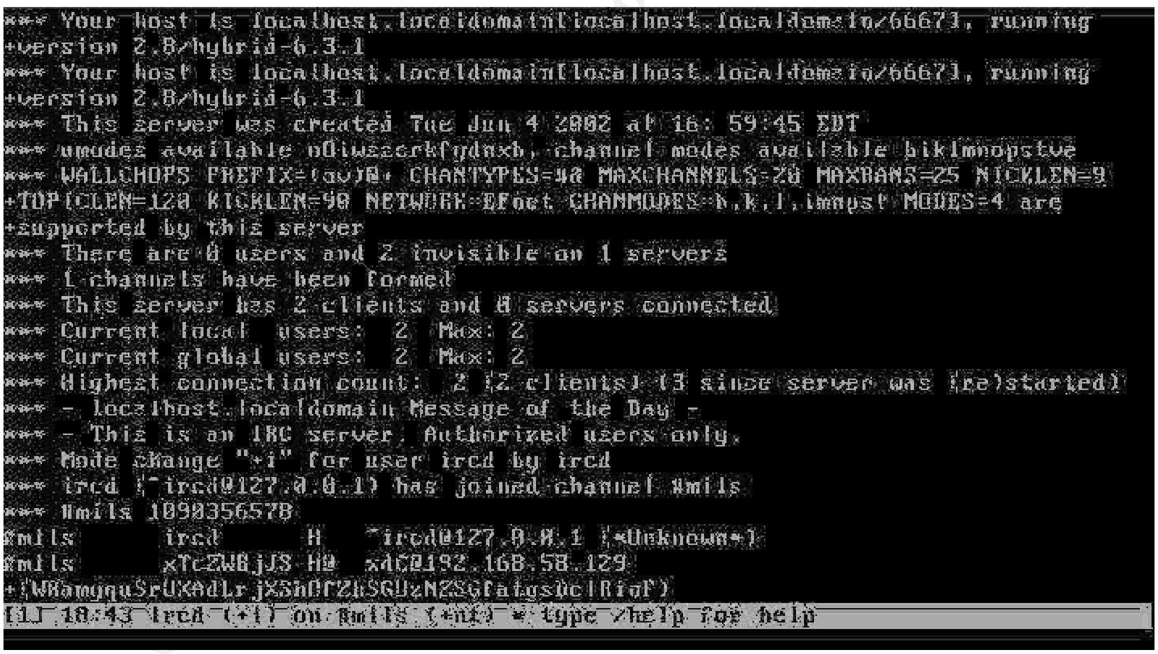
5.3.3. Conclusions so far

- o msrll.exe connected to the IRC server port 6667 on the Linux machine
- o msrll.exe provided the ident service on the infected Windows machine on port 113, in order to be able to respond to incoming ident-requests
- o it chooses the nick `xTcZWBjJS` to use in IRC. Randomly generated characters, the chosen nick changes every time the application connects to the server
- o it then joins the channel #mils
- o also, when the bot gets kicked off the channel, it joins back in automatically



This screenshot shows the perspective from another IRC client that I used on the Linux machine itself to connect to the IRC server, join channel #mils and list the users that are in the channel. Ircd is me, `xTcZWBjJS` is the 'user', the msrll.exe application on the infected Windows machine.

5.3.4. Conversation with the IRCBot

At this point it seems that the binary msrll.exe launches an IRC client to connect to a certain IRC server. An automated IRC client (i.e. connecting to a server and joining of a channel automatically, as well as sitting in a channel and waiting for commands) is also called an IRCBot.

Since we could not determine the commands that we can use by simply looking at the string output of the binary, we will issue some standard commands that may be common in some IRCBot implementations.

The only command we found working was the CTCP VERSION command that queries a user for the version information of the IRC client he/she is using:

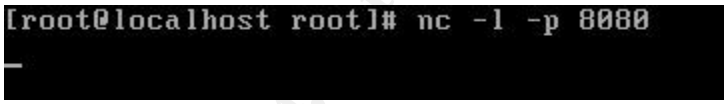
```
/ctcp xTcZWBjJS version
```

Response:

```
*** CTCP VERSION reply from xTcZWBjJS : mIRC v6.12 Khaled Mardam-Bey
```

This means the IRCBot pretends to be a mIRC version 6.12 client. A very common IRC client on the Windows platform.

The other ports Netcat was listening on (8080 and 9999) do not show any activity. This indicates that msrll.exe only tries to connect to those ports if the previous port is not available, some kind of 'fallback' to ensure irc server connectivity. This was also verified by testing: the IRC server was configured to listen on 8080 and 9999 subsequently; msrll.exe rotated through the port numbers until it found a server listening on one of the ports. Then it stopped trying to connect to any other port.



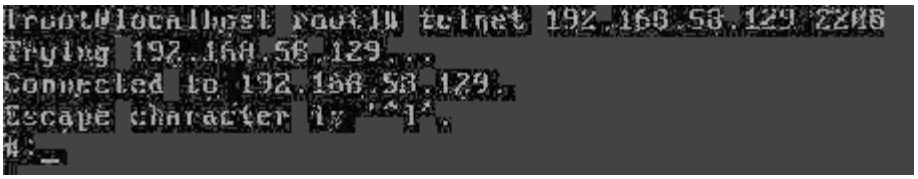
No activity on the other ports.

Shells on the infected Windows system?

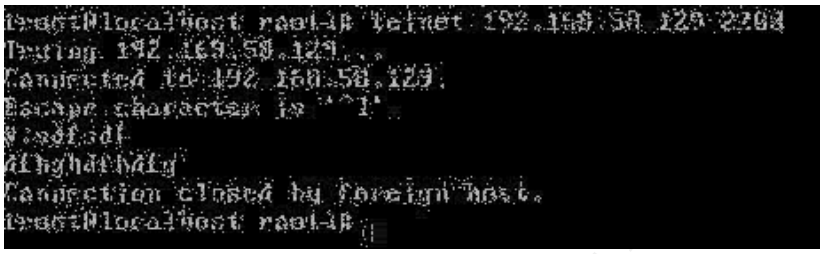
A netstat –an shows TCP ports 2200 and 2827 listening on the infected Windows system:

```
 Proto  Local Address          Foreign Address        State
  TCP    0.0.0.0:135            0.0.0.0:0              LISTENING
  TCP    0.0.0.0:445            0.0.0.0:0              LISTENING
  TCP    0.0.0.0:1025           0.0.0.0:0              LISTENING
  TCP    0.0.0.0:1026           0.0.0.0:0              LISTENING
  TCP    0.0.0.0:2200           0.0.0.0:0              LISTENING
  TCP    0.0.0.0:2827           0.0.0.0:0              LISTENING
  TCP    192.168.58.129:139     0.0.0.0:0              LISTENING
  TCP    192.168.58.129:2827    192.168.58.128:6667    ESTABLISHED
  UDP    0.0.0.0:445            *:*
  UDP    192.168.58.129:137     *:*
  UDP    192.168.58.129:138     *:*
  UDP    192.168.58.129:500     *:*
```

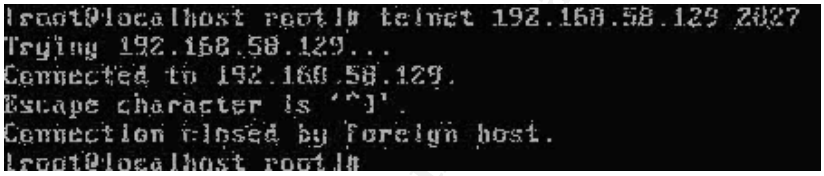
Connecting to port 2200 from the Linux machine results in a prompt:



Typing in random characters closes the connection after two lines of input (hitting 'Return' after each line):

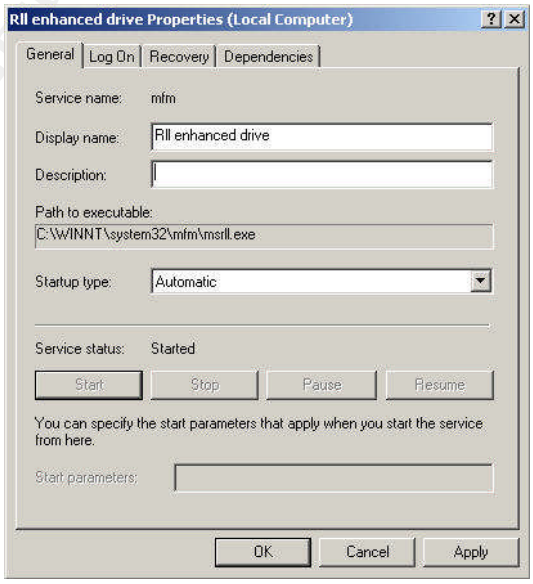


Connecting to port 2827 from the Linux machine results in a connection reset:



Whether it is possible or not to access a backdoor shell over these ports cannot be found out this way. The correct commands to access the shells – as well as the commands available to converse with the IRCBot – need to be determined through code analysis.

As stated before, msrll installs itself as a system service. An interesting property of it is that once an infected system was restarted and the 'service' has been started, not even the Administrator can stop it via the Settings - Control Panel – Administrative Tools – Services console: the control buttons are greyed out:



The only way to disable the service is to change the startup type to Manual or Disabled and reboot the machine.

6. Code Analysis

Code Analysis - 35 points

Use your laboratory setup to perform a code analysis of the unknown malware specimen. Describe the analysis in detail. Describe your steps and your use of your tools in detail. Explain the implications of the behavior of the malware.

Example procedures:

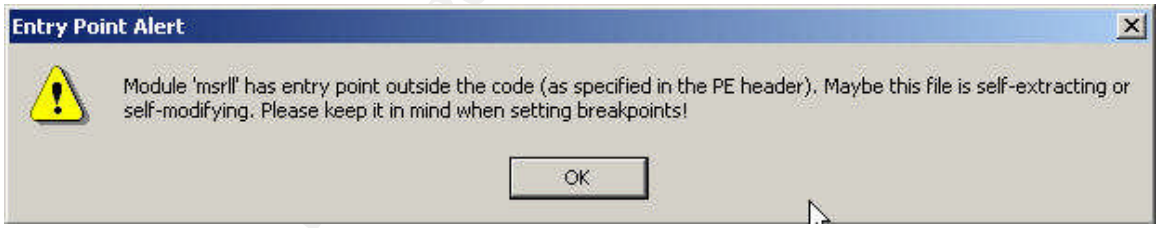
- Unpacking / Unencrypting
- Program code disassembly
- Debugging

6.1. Unpacking the file

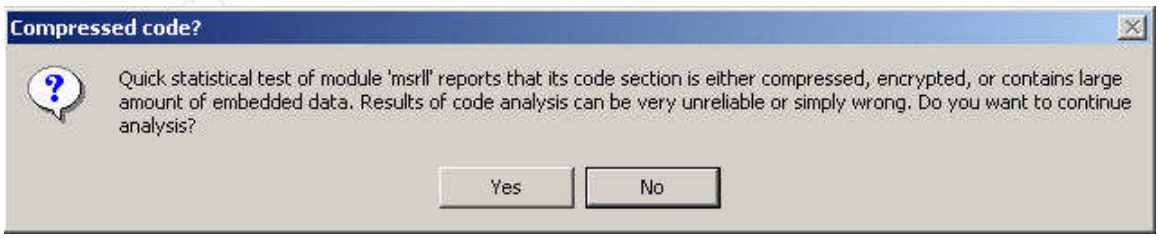
As already stated in the section “Properties of the Malware System”, these are the section headers in the msrll.exe binary:

```
00000178   00400178      0   .text
000001A0   004001A0      0   .data
000001F0   004001F0      0   .idata
00000218   00400218      0   .aspack
00000240   00400240      0   .adata
```

`.aspack` indicates that the file was packed using ASPack [ASPACK]



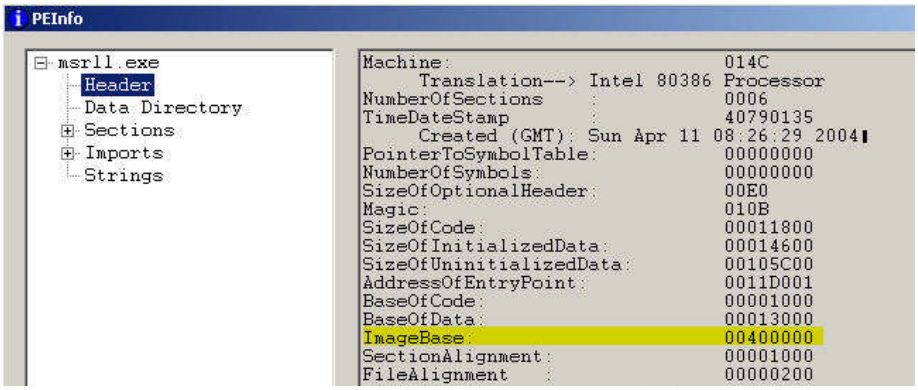
Since the binary might be self-modifying, it might be impossible to set correct breakpoints for debugging.



Also, the analysis can be unreliable and/or wrong, because of the compressed code. We need to unpack the binary.

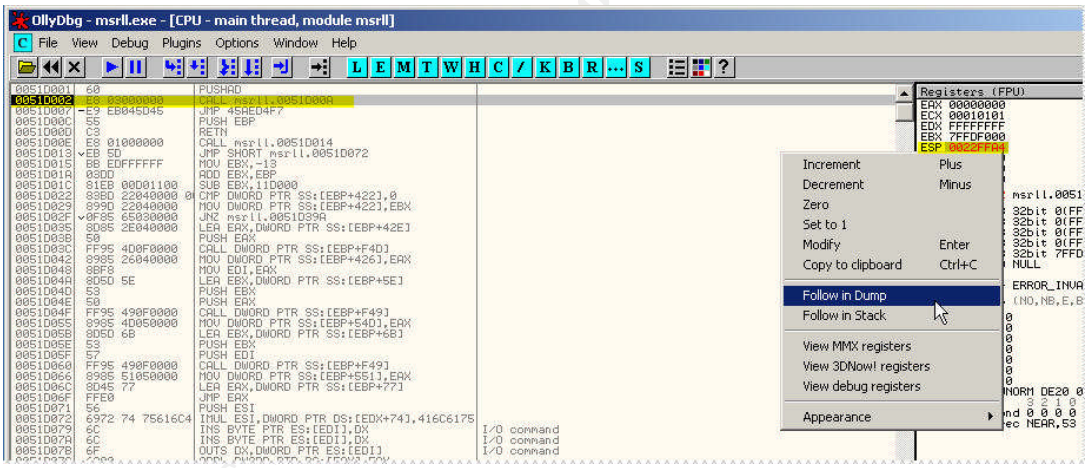
I found a walkthrough on how to unpack ASP-packed binaries with OllyDbg. [ASPACKUNPACK]

- since the file is packed, we need to find out what the original entry point is of the unpacked binary

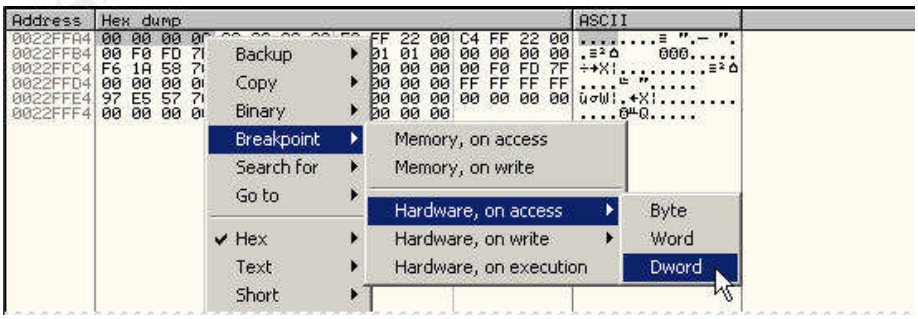


See highlighted above the image base (the base addresse) of the binary. We need this later to determine the offset of the original entry point.

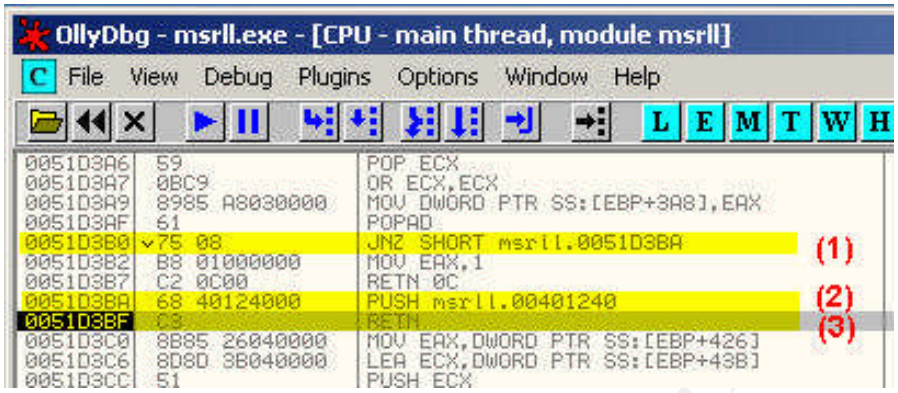
- open up the file in OllyDbg and press F8 to step to the CALL function
- right-click on the ESP register on the right and select 'Follow in Dump'



- in the dump window in the lower left of OllyDbg, mark the first four bytes, right-click and select 'Breakpoint – Hardware, on access – Dword'

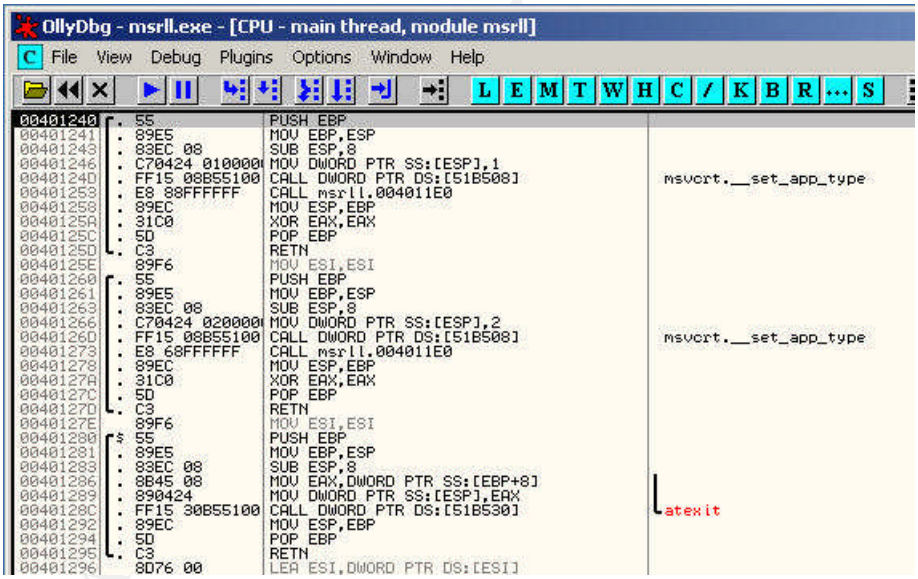


- hit F9 to start executing the binary, it will hit the breakpoint soon after

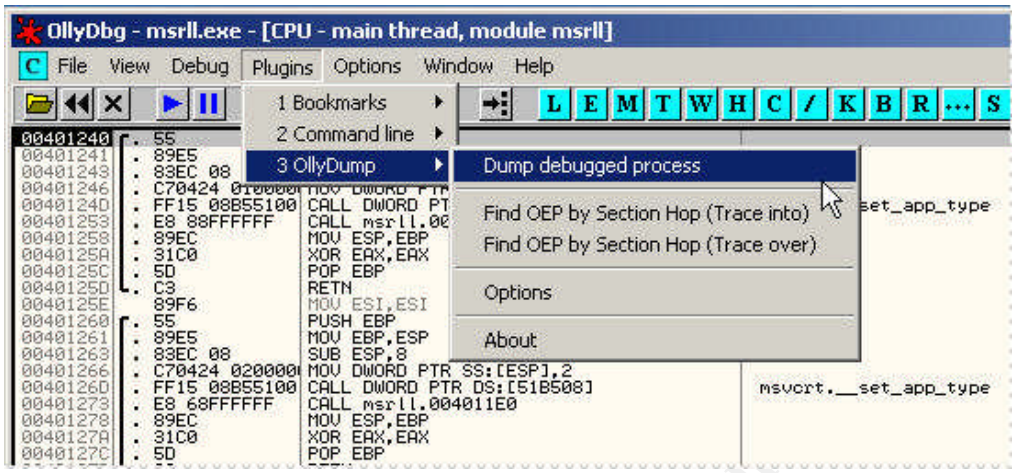


(1) denotes where the breakpoint was hit
(2) shows the address that will be pushed on the stack and
(3) will then return to that address, 0x00401240

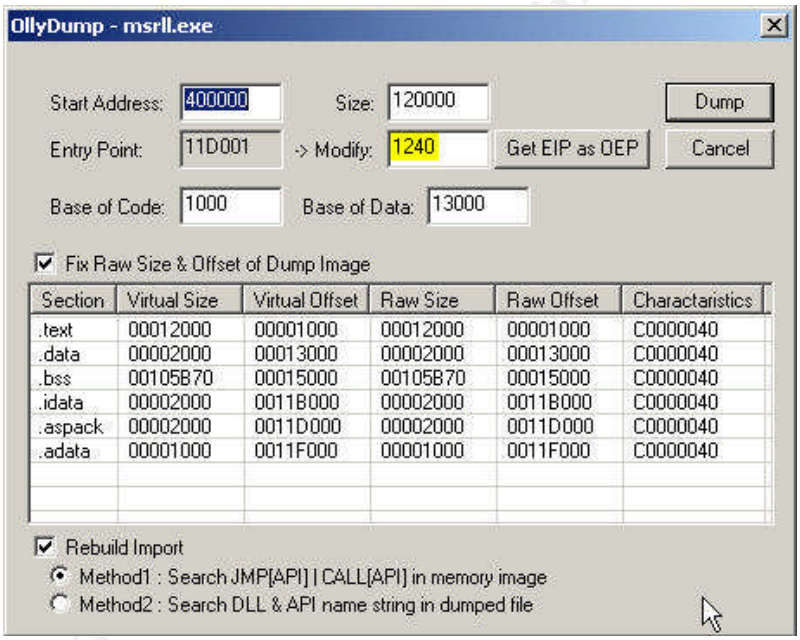
- hit F7 to trace into the code that resides at that address. This is the original entry point of the code
- Right-click on the code, select 'Analyse – Analyse code' to see the real code



- The address of the original entry point is 0x00401240. The imagebase of the code is 0x00400000. The offset of the original entry point is 0x00401240 - 0x00400000 = 1240.
- Select Plugins – OllyDump – Dump debugged process



- Modify the offset to show 1240, OllyDump may have already calculated that. Check 'Rebuild Import – Method1'



- dump the data into a new file, e.g. 'dumped_msrll.exe'

- close out the packed msrll.exe and load the newly created file into OllyDbg, then execute it. The binary works and the application connects to the IRC server the same way the packed original file did.

6.2. Analysing the unpacked file

Now that the file is unpacked, we can run it through Bintext to see if we find any useful information. Below you can find the interesting parts of the strings found.

```
File pos   Mem pos      ID   Text
========   =======      ==   ====

0000004D   0040004D      0   !This program cannot be run in DOS mode.
00000178   00400178      0   .text
000001A0   004001A0      0   .data
000001F0   004001F0      0   .idata
00000218   00400218      0   .aspack
00000240   00400240      0   .adata

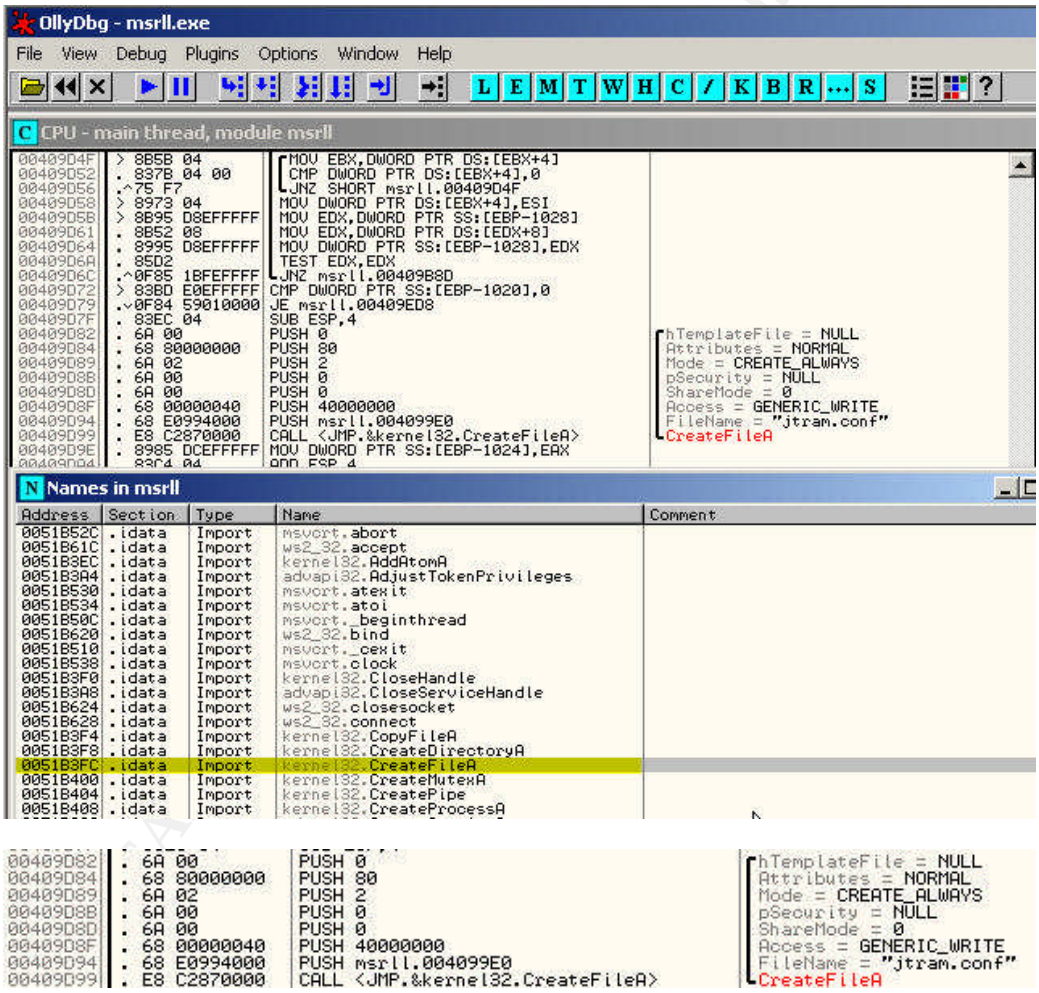
6.2.1. jtram.conf

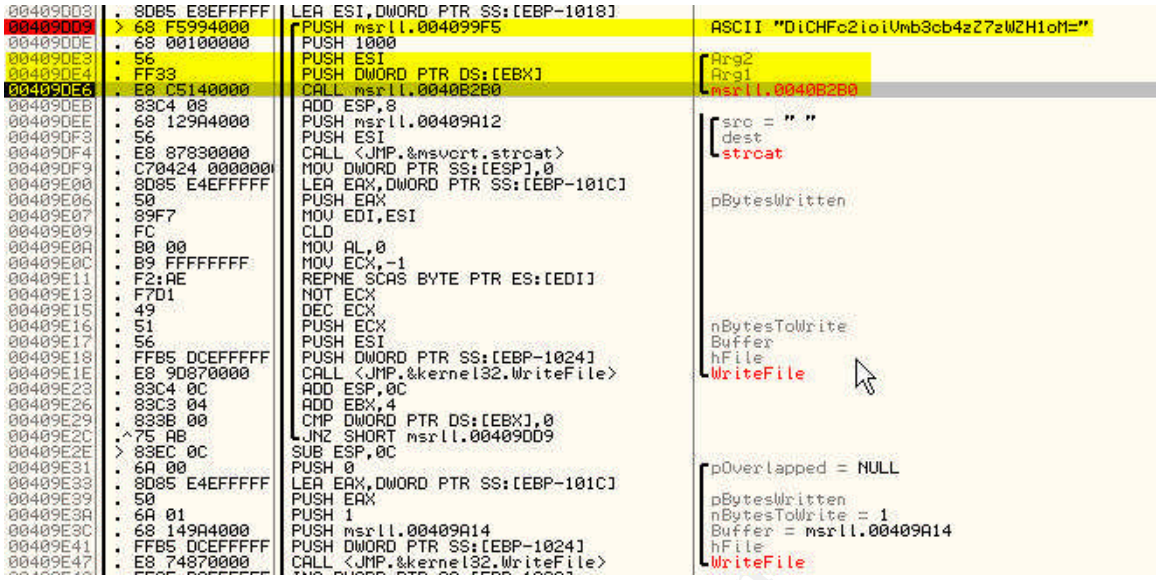
The file jtram.conf contains encrypted content. The file gets read and re-written every time the binary is executed. If we would be able to prevent the binary from encrypting the contents before the file gets written, the contents would be saved in clear text.

CreateFileA is a function responsible for creating files. CTRL-M in OllyDbg brings up all the symbolic names used in a module, so we use this to show the location of the function calls.

It occurs multiple times in the main module, however, the function that gets called at address 0x00409D99 refers to jtram.conf, as can be seen below.

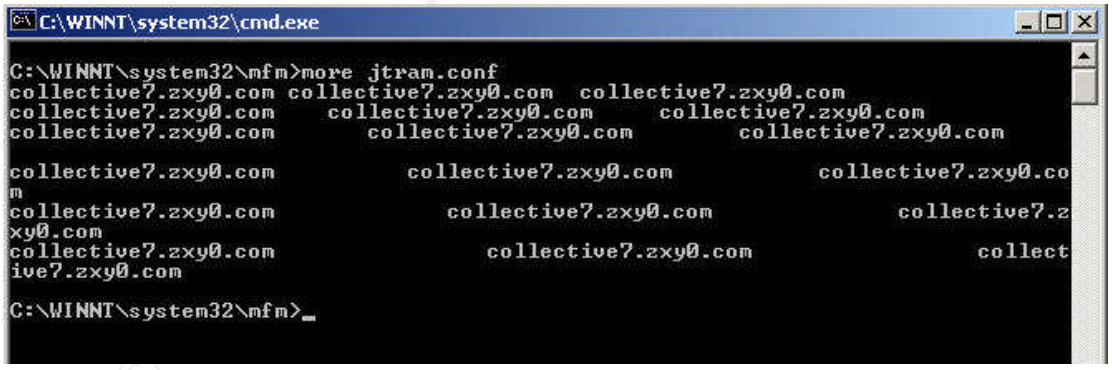


Immediately thereafter, we see a string that seems to be randomly generated, a function call and a string operation, strcat(), to concatenate strings. A breakpoint was set at the 'push' to stop the program at that point.



The function call at 0x00409DE6 XORs the random string and the string that should be 'encrypted'. Putting NOPs where the function call is prevents this from taking place.

Continuing the program, the file jtram.conf gets rewritten, with the content in cleartext.



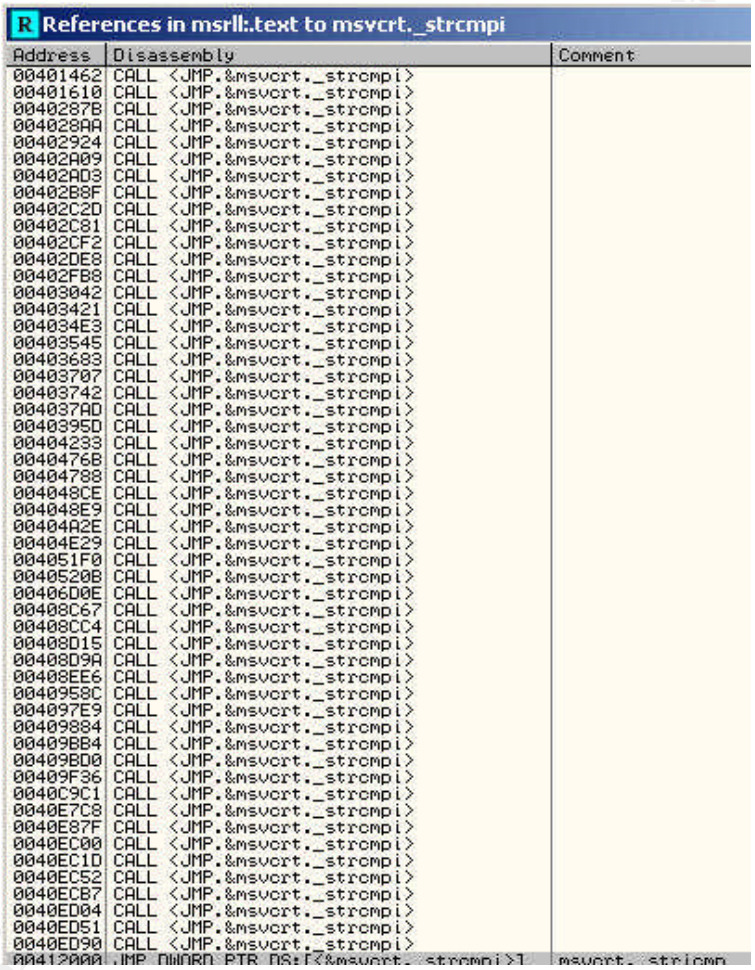
It is unclear why the file gets rewritten every time the binary gets executed. The content (collective7.zxy0.com) gets read out and written back every time the program is run.

6.2.2. Control of the IRCBot

To see how the IRCBot is controlled, we will check for the occurrence where string comparison functions are being used in the module, as it will be there where the input of the IRC channel will be processed.

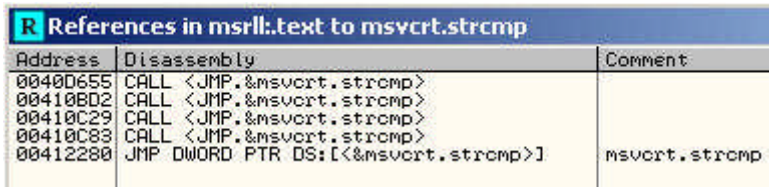
strcmpi() compares two strings, regardless of case.

Occurrences of strcmpi():



strcmp() compares two strings, however, it is case-sensitive.

Occurrences of strcmp():



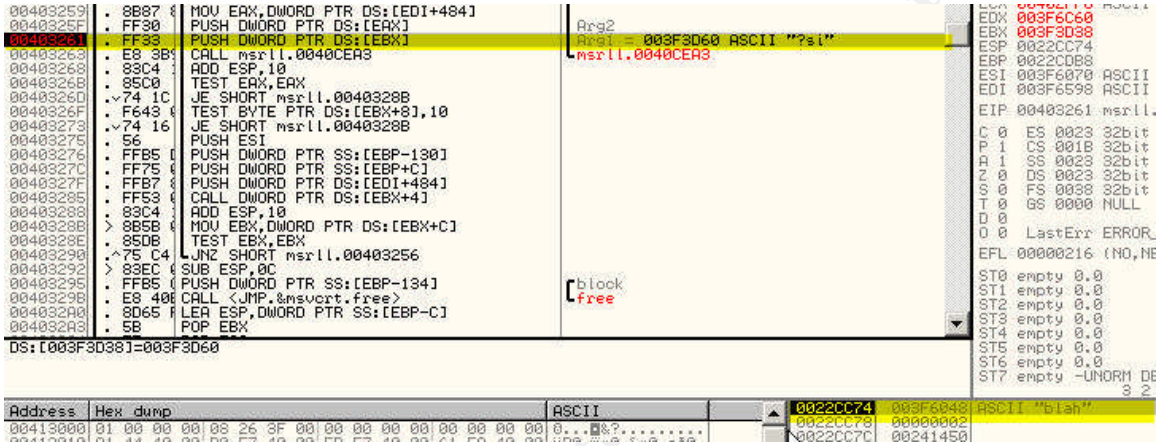
We will work our way through all these function calls, starting with the strcmpi calls.

This is done on a ‘clean’ – unpatched, yet unpacked, version of the msrll.exe.

The string comparison commands are narrowed down to the ones that get executed whenever something is input on the IRC channel.

6.2.2.1. IRCBot commands

There is a function call at 0x00403263 that has 2 arguments as parameters: the input from the IRC channel and whatever commands are allowed.



The push at 0x00403261 points to a memory address, 0x003F3D60 (containing ASCII “?si”). Looking at the memory region 0x003F0000 via the Memory Map – “Dump in CPU”, we can see the commands. I saved the dump into a file and parsed it with a Perl script [PERLSCRIPT] I wrote for all occurrences of “?<command>” with the following results, sorted by alphabet:

```
?!fif           ?exec           ?lsmod          ?run
?akick          ?fif            ?md5p           ?say
?aop            ?free           ?mkdir          ?set
?cd             ?get            ?move           ?si
?clone          ?hostname       ?msg            ?sklist
?clones         ?hush           ?nick           ?smurf
?con            ?insmod         ?op             ?ssl
?copy           ?join           ?part           ?status
?crash          ?jolt           ?ping           ?sums
?dcc            ?jump           ?play           ?syn
?dccsk          ?kb             ?ps             ?uattr
?del            ?kill           ?pwd            ?udp
?die            ?killall        ?raw            ?unset
?dir            ?killsk         ?reboot         ?update
?dump           ?login          ?rmdir          ?uptime
?echo           ?ls             ?rmmod          ?wget
```

This looks like a relative complete list of probably valid commands to control the IRCBot.

6.2.2.2. Finding an authentication section

Looking through the code sections, one stands out: it talks about ‘PASS’ and ‘logged in’. The section starts at address 0x00415B1B.

I am not sure when the program jumps to this section. Checking the call trace (CTRL-K in OllyDbg) for every reasonable command in this section does not reveal anything. I am guessing that the command that jumps to this section gets its jump address dynamically, by pointing at register content rather than fixed addresses. If the program can be tricked to jump to this section, we may be able to gain control over the bot.

The place where the authentication has been successfully verified might be at around 0x00405B87. That is the location in the code where arguments are getting supplied to the function call at 0x00405B93 that then jumps over to 0x00404481.

I am lacking the assembler knowledge to accomplish the jump to this authentication section or to 00x00404481 without crashing the program (I tried modifying calls to point to that location instead, but got access violations), so this is where I stop the code analysis section of this paper.

7. Analysis Wrap-Up

Analysis Wrap-Up - 15 points

Based on your analysis, what is the malware specimen's capabilities? What does it do? Who would use the program? What defensive measures can you derive from your analysis to prevent future attacks by this specimen and eliminate current infections? What other information can be deduced about the program?

7.1. Capabilities of the Specimen

- installs itself as system service under fake name ('RLL System Drive') that starts automatically on system start-up
- features an integrated IRCBot that connects to an external IRC server, joins a predefined channel and waits for orders
- cycles through different ports on the IRC server in case a port is not reachable
- when kicked off channel, joins back in automatically
- opens a shell on the infected machine on port 2200
- vast list of commands enable in-depth control of the IRCBot
    - IRC-typical commands such as DCC support, commands for maintaining channel control
    - Remote control of the infected system: show contents of directories, remote download files, crash/reboot the system, modify filesystem (mkdir etc), execute commands on system (run)
    - Clone
    - ability to launch syn-, smurf- and jolt-based Denial-Of-Service attacks [SMURF], [JOLT2]

Note: regarding the comments about the list of commands above: since I was not able to gain control over the IRCBot in the previous section, I assume that the commands that were found in memory are valid commands. I interpreted the functionality of those commands by the names of those (i.e. ?jolt launching a jolt attack, ?mkdir creating a directory on the infected host etc).

7.2. Behaviour

Summary of behaviour: upon execution, the binary

- creates a directory in Winnt\System32 called mfm
- copies itself over
- executes itself from the new location
- tries to read in a configuration file, jtram.conf in that directory and re-writes that file. If the file does not exist, it uses its default configuration (the IRC server it connects to is set to collective7.zxy0.com)
- deletes the original file
- installs itself as a system-service, using a description of 'RLL enhanced drive', set to start automatically at system start-up
- opens listening ports on the infected machine, TCP 113 for Ident service to supply information to querying IRC server/s, TCP2200 for a backdoor shell
- connects to an IRC server, trying pre-set ports until successful. Uses randomly created nick name and user identification string
- logs into channel #mils and waits for input

7.3. Audience that would use this Malware

The target audience that would use this malware would be people desiring to gain control over Windows-based host systems. The program can be used to control and modify an infected system, provide support in controlling IRC channels, host files for (illegal) distribution (files would be accessible on the infected system per IRC DCC sessions) and to launch Denial-Of-Service-based attacks on other systems.

7.4. Defensive Measures

The following measures should always be implemented:

- users must be educated about the risks involved with accessing (local and remote) sites in the Intranet and the Internet; the dangers of visiting untrusted sites; the use of untrusted applications; the risks involved with e-mail (opening attachments for example)
- systems must always be patched up to the latest revisions to make sure that the operating system or installed applications do not facilitate a local or remote compromise
- hosts need to be locked down according to strict security standards, locally as well as on the network-level. Defense-in-Depth should always be employed: the securing of devices, systems, applications, networks, access on multiple levels to enable a maximum level of protection
- local protective and defensive measures should include the use of anti-virus scanners, host-based firewalls, strict security policies that are applied locally and on the network as a whole
- network-based defensive measures should include intrusion detection and –prevention systems, firewalls, router/switch-based access lists
- applications that can be used by users and that access untrusted destinations should be restricted to an absolute minimum (e.g. only use internal instant messaging if at all, prohibit the use of other instant messengers, chat applications like IRC etc, restrict website access to a limited number of sites – at least communicate what kind of websites are not approved to be accessed)

7.5. Other information

Using the name of the configuration file, jtram.conf, as keyword with Google, I found out that "Troj/Tometa-A - BKDR_TOMETA.A" is the real name of the program. It is classified as a Trojan.

Excerpts from the information page [TRENDMICRO]:

```
[…]
Details:

Installation and Autostart

Upon execution, this memory-resident backdoor program creates the folder mfm in the
Windows system directory. It then drops the following files in the said folder:

MSRLL.EXE – main malware executable
JTRAM.CONF – non-malicious data file used by the malware
It creates the following autostart entry on Windows 95, 98, and ME to ensure its
execution at every system startup:

HKEY_LOCAL_MACHINE\Software\Microsoft\
Windows\CurrentVersion\Run
Rll enhanced drive = "%System%\mfm\msrll.exe"

(Note: %System% is the Windows system folder, which is usually C:\Windows\System on
Windows 95, 98 and ME, C:\WINNT\System32 on Windows NT and 2000, and C:\Windows\System32
on Windows XP.)

On Windows NT, 2000, and XP systems, it attempts to add itself as a service using the
name Rll enhanced drive by adding the following registry key:

HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\mfm

Backdoor Capability

This backdoor program attempts to connect to the Internet Relay Chat (IRC) server of
collective7.zxy0.com. It cycles through remote ports 6667 (default IRC port), 9999, and
8080 when attempting to connect to the server.

Once connected, it then joins a channel, where it awaits for commands from a remote user.
It also listens for commands from the TCP port 2200.

Other Details

It arrives Aspack-compressed.
[…]
```

Since I am running Windows 2000, as mentioned in the first section of this paper, the trojan did not create a key under `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\ CurrentVersion\Run`, it only installed itself as a service.
