Assignment 1 The State of Intrusion Detection

Got Correlation? Not Without Normalization

Introduction

There have been many attempts by various groups to develop a standard that can take an event from any source and convert it to a standard format. Why would an analyst want something like this? Lets look at what steps an analyst might use to determine if their network may have been compromised. A network Intrusion Detection System (IDS) detects a web exploit targeted at a web server. First the analyst would review the perimeter router logs to see if the router passed the packet that triggered the alert. Based on the nature of this exploit, the probability that the packet was forward through the router is high. This is due to the fact that the exploit uses a standard TCP port (80). Second an analyst would want to review the firewall logs to see if this was blocked by any of the filters which are in place there, since the firewall is statefull it could have blocked something that the router may have passed as acceptable traffic. At this point the analyst is sure that the packets reached the webserver so further investigation is necessary. Since the exploit reached the web server the integrity of that box must be checked.

Third, to check the integrity of the webserver and look at all traffic that originated from the compromised box the analyst would run Tripwire, which is a file integrity checker using MD5 checksums, to see which files if any have been accessed or modified.

Fourth the analyst would look at the Syslog output or the EventLog from that server, as well as pull the tcpdump data off the dedicated tcpdump host for that segment for the time surrounding the attack to see what actually happened. Already the analyst would have accessed four different systems and looked at five different types of logs. That's a lot of work, and it takes time that could be spent securing the network and cleaning the compromised server to make sure that no other systems can be affected. It is preferred to have all the relevant data located in one logging facility allowing the analyst to sort by time to look at the sequence of events as they occurred.

In the art of intrusion detection there are many sources from which we can obtain information that can lead to an explanation, or the conformation of an exploit targeted at one of your network systems. Confirming that you have been the victim of an attack is like putting together a puzzle; the problem is that the pieces are all from different puzzles. When investigating an incident an analyst is dealing with a heterogeneous environment, where each device has a different logging format and reporting mechanism. He will also have logs from remote sites, where security policies and procedures will be different, different types of network devices, host based IDS, network based IDS, and different types of operating system and application logs. That's why the Industry needs normalization and correlation.

Correlation

What is correlation? Correlation is derived from the word correlate that means to be in or bring into mutual relation. That's the dictionary definition, but the "information security world" interprets correlation as having the ability to access, analyze, and relate different

attributes of events from multiple sources to bring something to the attention of an analyst that would have went unnoticed otherwise. Referring to the earlier example, correlating the accepted packet on the perimeter router, the accepted packet on the firewall, the IDS alert that detected a web exploit headed for the webserver, all coming from the same source IP address, along with the results of the integrity check, make it easier to confirm and reinforce the determination that the web server was indeed compromised and further action is necessary. As of now there is no commercially available tool that allows for this capability because the logs from all these devices are stored in different formats, and in different locations. In analysis it would be ideal to access all the logs from the entire enterprise from a single console, and have them stored in one common database. A database would be the most logical central storage facility because of the functionality it would allow for, such as querying and reporting. To accomplish this an analyst would first need to get the logs from all these devices, normalize them, and insert them into the database so they could be stored in a common format. In order to have real correlation we must start with normalization.

Normalization

How does normalization, meaning conforming to an accepted standard or norm apply to hunting down hackers and examining log files? Picture a typical enterprise environment, it consists of many different types of network devices ranging from border routers, VPN devices, to firewalls, to authentication servers, along with an even wider range of application servers like webservers, email servers, and always-critical database servers. All these different devices generate logs that are critical to an analyst who's responsible for the security of the site. It is seldom if ever that two different manufactures or vendors will use the same logging mechanism, format their logs differently. For example a Cisco PIX will not report an accepted packet the same as a Checkpoint firewall or even the same as a Cisco Router. The fact that the formats are all different makes it virtually impossible to store the log data in a common location such as a database without normalizing the events first.

The following are logs from different network devices all reporting on the exact same packet traveling across the network. These logs represent a remote printer buffer overflow that connects to IIS servers over port 80.

CheckPoint:

```
"14"  "21Dec2001"  "12:10:29"  "eth-s1p4c0"  "ip.of.firewall"  "log"
"accept"  "www-http"  "65.65.65.65"  "10.10.10.10"  "tcp"  "4"  "1355"
""  ""  ""  ""  ""  ""  ""  ""  ""  "firewall"  " len 68"
```

Cisco Router:

```
Dec 21 12:10:27: %SEC-6-IPACCESSLOGP: list 102 permitted tcp
65.65.65.65(1355) -> 10.10.10.10(80), 1 packet
```

Cisco PIX:

```
Dec 21 2001 12:10:28: %PIX-6-302001: Built inbound TCP connection
125891 for faddr 65.65.65.65/1355 gaddr 10.10.10.10/80 laddr
10.0.111.22/80
```

Snort:

```
[**] [1:971:1] WEB-IIS ISAPI .printer access [**]
[Classification: Attempted Information Leak] [Priority: 3]
```

```
12/21-12:10:29.100000 65.65.65.65:1355 -> 10.10.10.10:80
TCP TTL:63 TOS:0x0 ID:5752 IpLen:20 DgmLen:1234 DF
***AP*** Seq: 0xB13810DC  Ack: 0xC5D2E066  Win: 0x7D78  TcpLen: 32
TCP Options (3) => NOP NOP TS: 493412860 0
[Xref => http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2001-0241]
[Xref => http://www.whitehats.com/info/IDS533]
```

All these formats are different and would be impossible to store in a database with out normalizing them first. Looking at the checkpoint record it contains the following fields: event id, date, time, firewall interface, IP address of the firewall interface, logging facility, action, service, source IP, target IP, protocol, source port, some checkpoint specific fields and then the size of the datagram. This is the most obscure format and it's especially hard to read with all the empty fields that are represented by double quotes. Now the Cisco router has a different format the fields it populates are date, time, logging facility, event name, source IP, source port, target address, target port, and number of packets. The Cisco PIX, which one would expect to have the same format as the Cisco router since they are made by the same company, uses date, time, event name, source IP, source port, translated address or target address, target port, local address, and local port. The final record is the Snort alert that claims this traffic was malicious. The fields Snort populates are exploit or event name, classification, priority, date, time, source IP, source port, target IP, target port, protocol, TTL (Time to Live), type of service, ID, IP length, datagram length, tcp flags, sequence number, acknowledgement number, window size, and tcp length. Snort also includes additional data such as references to investigate this exploit.

So how could these events possibly be stored in a common format in a database? It must first be decided which fields are interesting and develop a schema to accommodate the different fields that are populated by these devices. Choosing the fields must be content driven not based on semantic differences between what Checkpoint may call target address and what Cisco calls destination address. Next a parser must be coded to pull out those values from the event and populate the corresponding fields in the database. So pretend that the following table is from a database containing these alerts after they have been normalized.

Date	Time	Event_Name	Src_IP	Src_Port	Tgt_IP	Tgt_Port	Device_Type	Additional_data
21-Dec-01	12:10:29	accept	65.65.65.65	1355	10.10.10.10	80	CheckPoint	
21-Dec-01	12:10:27	list 102 permitted tcp	65.65.65.65	1355	10.10.10.10	80	Cisco Router	
21-Dec-01	12:10:28	Built inbound TCP connection	65.65.65.65	1355	10.10.10.10	80	Cisco PIX	
21-Dec-01	12:10:29	WEB-IIS ISAPI .printer access	65.65.65.65	1355	10.10.10.10	80	Snort	TCP TTL:63 TOS:0x0 ID:5752 IpLen:20 DgmLen:1234 DF ***AP*** Seq: 0xB13810DC Ack: 0xC5D2E066 Win: 0x7D78 TcpLen: 32 TCP Options (3) => NOP NOP TS: 493412860 0

These are the same four events we looked at earlier except they have been normalized. This would be ideal for an analyst investigating an incident. With the data organized like this one could pull all records containing a value that's of interest or sort by any field that may be relevant. This would make it extremely more efficient to investigate what

occurred during the course of an attempted exploit and whether or not the attack was indeed successful. The problem is that just putting this data into a spreadsheet manually was easy but to get a program to do it would be much more difficult. For instance the checkpoint firewall reports target port as www-http not 80 like most devices. Therefore there must be a lookup mechanism to ensure that www-http gets translated into port 80 otherwise this value would be useless in correlation. Another complication would be converting the date/timestamps. Since the devices all use a different format the program couldn't just parse out the time stamp reported by the device it would also need to convert it to a common format such as GMT.

Developing a Standard

What is needed industry wide is a standard that supports interoperability. There have been several groups of engineers that have tried to accomplish this task. The first group recognized by Security Professionals is the CIDF working group, which was sponsored by DARPA (Defense Advanced Research Projects Agency). CIDF stands for Common Intrusion Detection Framework. The goal of the group was to provide common message formats and exchange procedures for interoperability and a common understanding between intrusion detection systems. They discovered that it was necessary to express the information in a format that all of the systems could understand and interpret. CIDF seems to have phased out but it has provided a framework and a set of guidelines that have been partially adopted by another group. The Network Intrusion Detection An Analyst's Handbook says "The effort (CIDF) did a great service to the community, however, by trying to establish a vocabulary to discuss intrusions." So the work was not in vein it just never became accepted as the industry standard. According to the SANS course material, "The current status of CIDF is unclear, though some of it's efforts may have been overtaken by the Intrusion Detection Working Group (IDWG)."

The IDWG is another group of engineers who are working towards developing a standard data format called IDMEF. IDMEF is Intrusion Detection Message Exchange Format. Some of the benefits that IDMEF could provide in future implementations range from a single database containing logs from different security products, to the foundation for an event correlation system which could accomplish cross vendor and cross platform correlation. IDMEF is based on an object orientated data model that allows for flexibility. Different alerts will have different needs; some will offer much more information than others requiring additional objects to be added to the model. They chose an object oriented model because of the ability to subclass which allows them to extend the model, meaning that one system may not know what all the objects in the alert mean but they will still be able to interpret the values which are of concern to them. In their white paper the IDWG states, " The goal of the data model is to provide a standard representation of the information that an intrusion-detection analyzer detected an occurrence of some unusual activity. These alerts may be simple or complex, depending on the capabilities of the analyzer that created them." There has yet to be any large-scale implementation of IDMEF in the commercial market but in the open source world a company called Silicon Defense (www.silicondefense.org) has implemented an IDMEF compliant plugin for the Snort NIDS. The biggest problem is getting the commercial IDS vendors to see a value in interoperability. They don't want people to be able to mix and

match their expensive commercial products with open source products that you can get for free. From their business perspective it is not high on the priority list, they would much rather force you to stick with their product line whether it solves your problem or not.

Conclusion

In the ever-changing world of intrusion detection there is a definite need for data normalization. Looking at logs in twenty different formats and on four different consoles, as well as trying to find all the events across the network that may pertain to the attack being investigated is one of the hardest parts of any analyst's job. There is no way to visualize the sequence of events when they are all stored in different locations, and visualization is one of the keys to deciphering a network attack. The ability to relate and analyze events from a multitude of vendors, from a variety of intrusion detection devices, and from all the event generating devices that make up the common enterprise would make every analyst's puzzle a little easier to solve.

Assignment 2 Network Detects

Introduction

I collected the following detects from a network that I have access to as part of my job. Please note that the security policies of target.net are not under my control nor do I have any influence as to getting them to change their policies. I do not agree with most of the security measures they have in place.

I setup the IDS devices on their network so that I have snort running outside the firewall with a passive interface. I have also disabled ARP so that there is no way to gain access to the snort box from any external source. I also have another workstation running tcpdump for packet analysis, configured in the same manner. I have included a simple topology of the network that generated these detects. For the purpose of this paper I have labeled it www.target.net. The name is entirely fictitious and makes no reference to a real company.

TCPDUMP Output From These Alerts
Alert1

I ran the tcpdump output through ethereal and generated a text file because it is much easier to read. What these packets show is the initial connection to port 21 on my FTP server from the attacker. Frame 9 contains the exploit that triggers the first snort alert.

Source of Trace
This trace came from a network that I have access to.

Detect was generated by
These alerts were generated by snort version 1.8.3 running with the full rule set available at www.snort.org. These alerts were generated by the following snort rules.

```
alert tcp $EXTERNAL_NET any -> $HOME_NET 21 (msg:"FTP EXPLOIT wu-ftpd
2.6.0 site exec format string overflow Linux"; content: "|31c031db
31c9b046 cd80 31c031db|"; flags: A+; reference:bugtraq,1387;
reference:cve,CAN-2000-0573; reference:arachnids,287;
classtype:attempted-admin; sid:344; rev:2;)

alert tcp $EXTERNAL_NET any -> $HOME_NET 21 (msg:"FTP site exec"; cont
ent: "site exec"; nocase; flags: A+; reference:bugtraq,2241;
reference:arachnids
,317; classtype:bad-unknown; sid:361; rev:2;)
```

The second of these snort rules should be modified please refer to the defensive recommendations section as to why and how.

The raw packet data was gathered from a host outside the firewall running tcpdump and logging to a repository. I grabbed the tcpdump output after I found these alerts and wrote several filters and then loaded that into ethereal and saved the output to a text file because it is easier to read.

Probability the source address was spoofed
I don't believe that the source addresses were spoofed because in order for this attack to be successful a three-way handshake must take place.

Description of attack
This attack is targeted at FTP servers running Wu-Ftpd 2.6.0. Wu-Ftpd is a very common version of ftp that is shipped with many Linux distributions, and was developed by Washington University. Because of insufficient input string validation an attacker can execute arbitrary commands on the remote host as root. There are CVE, (CVE # 2000-0573) and cert advisories located at the following links.
http://www.cert.org/advisories/CA-2000-13.html
http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0573

In this case the targeted host was running a vulnerable version of Wu-Ftpd and this attack was successful. The ftp server also allowed for anonymous login, which is the default setting when you build an ftp server. The attacker issued system commands on the host and actually copied the shadow password file off of the system. I know that this attack was indeed successful because of a packet I saw later in the dump that showed the

transfer of the shadow password file. This traffic is indicated in the following packets. If you look at the payload of the first packet you will see the command being issued: cat /etc/shadow. The second packet contains the contents of the shadow file including the user name root. Indicating that the command executed successfully. I have highlighted both of these payloads to make them easy to find.

Attack mechanism

With in the FTP service there is functionality called site exec that allows logged in users to execute a restricted subset of commands on the ftp server. The following explanation is from the cert advisory regarding this exploit.

> "The wu-ftpd "site exec" vulnerability is the result of missing character-formatting argument in several function calls that implement the "site exec" command functionality. Normally if "site exec" is enabled, a user logged into an ftp server (including the 'ftp' or 'anonymous' user) may execute a restricted subset of quoted commands on the server itself. However, if a malicious user can pass character format strings consisting of carefully constructed *printf() conversion

characters (%f, %p, %n, etc) while executing a "site exec" command, the ftp daemon may be tricked into executing arbitrary code as root."
http://www.cert.org/advisories/CA-2000-13.html

If you look at several of the packets that I have included you will see the use of the %f character as well as %x.

```
40  d199 5349 5445 2045 5845 4320 6161 6161   ..SITE EXEC aaaa
50  6161 6161 6161 6161 6161 6161 6161 6161   aaaaaaaaaaaaaaaa
60  6161 6161 6161 6161 6161 6262 6262 74d0   aaaaaaaaaabbbbt.

40  cf70 5349 5445 2045 5845 4320 2578 2025   .pSITE EXEC %x %
50  7820 2578 2025 7820 2b25 7820 7c25 780a   x %x %x +%x |%x.
```

There is a very detailed description of this exploit containing the exact source code that creates the vulnerability is located at the following link.
http://www.securityfocus.com/archive/1/66544
In this trace the attacker has utilized this vulnerability to gain access to the /etc/shadow file. The compromised host was running RedHat 6.2 and was used as an FTP server for the company for which it belonged.
Why would an attacker want to use this exploit to gain access to the shadow file. Well there are many reasons first of which it will give him a list of all the user names on that system. With that information he has already solved half the problem into breaking into other systems. Most of the time there will be user names in that file still containing the default passwords. This would be the case when you have an admin who makes everyone a user account and tells him or her to be sure to change his or her passwords. Now how many times have you heard that and left your password as the default 'password'. Hopefully never, but there are many users who are not security aware and they find it easier to remember default or welcome than a difficult password including special characters and numbers. Just having a list of valid user names gives an attacker just that much more of an advantage. They can be used to brute force logon attempts, not a very stealthy way but some time effective.
The shadow file also contains the encrypted password for each user. Depending on the length and the complexity of the password they can be cracked within a reasonable amount of time.

Correlations

The honey net group detected the following alerts. These alerts were most likely triggered by similar activity.
http://project.honeynet.org/scans/scan19/scan/som6/timeline.xls

00:55:58.209849	[ALERT] FTP site exec	207.35.251.172:2243	192.168.1.102:21
00:55:58.372588	[ALERT] FTP site exec	207.35.251.172:2243	192.168.1.102:21

There is a brief discussion of this exploit at the following link.
http://www.sans.org/y2k/072100.htm
They are basically discussing how this vulnerability was around for a while, at least eight months before it was ever posted to bugtraq or CVE. The reason that they know this is

because the author of the code states, "WuFTPD: Providing *remote* root since at least1994"

Evidence of active targeting
This was definitely active targeting. This is an FTP exploit targeted at an FTP server. The attacker may have scanned the network prior to these alerts in order to determine which hosts were running ftp services.

Severity
Criticality = 5 This server is a part of the network infrastructure for target.net and is required for business purposes.

Lethality = 5 Any attack that gives an attacker root on one of my network devices is considered to be extremely lethal. On this case the attack was successful and the attacker gained information and maybe more.

System Countermeasures = 0 This system had no counter measures as it was exploited. The server was running a vulnerable version of ftpd and the attacker took advantage of that.

Network Countermeasure = 0 This server is in the DMZ and is allowed to be accessed from the internet. There are no ACL's in place or rules on the fire wall that would prevent this attack.

(Criticality + Lethality) –
(System Countermeasures + Network Countermeasures) = Severity

(5 + 5) – (0 + 0) = 10

This attack is extremely severe such proves this formula. There was a successful attack and if you look at the severity it is a 10. A 10 represents the highest severity possible.

Defensive recommendation
First off I would recommend rebuilding this server as it has been compromised you don't know what else may have happened to it. Unfortunately tripwire was not installed at the time so a file comparison couldn't be done to see what other files may have been accessed or modified. I would recommend in the future having tripwire installed on all production servers. Tripwire is available at www.tripwire.org I would also recommend upgrading the version of Wu-Ftpd to the latest version. Upgrades for the version of RedHat are available at the following link. ftp://updates.redhat.com/6.2/i386/wu-ftpd-2.6.0-14.6x.i386.rpm
Another thing to consider would be implementing access controls on the firewall to only allow specified IP addresses to access this FTP server. Since this attack is contingent upon being logged into the ftp server I would recommend disabling anonymous access.

As I stated earlier the second snort rule that is looking for the "site exec" string in the payload should be modified. The reason for this is due to the fact that that the attacker could put two spaces in the command and therefore bypass the IDS. I would recommend building a dynamic rule. By dynamic I mean using the regex option. "The regex option allows content options to specify wildcard options. The wildcards behave more like shell globbing than Perl-type regular expressions. A '*' in the content string, along with the regex modifier is interpreted to mean "any character, any number of times." http://www.snort.org/docs/writing_rules/chap2.html#tth_chAp2 This is from the Snort Users Guide written by Marty Roesch.
The following rule has been modified and I would recommend replacing the current snort rule with this one.

```
alert tcp $EXTERNAL_NET any -> $HOME_NET 21 (msg:"FTP site exec"; cont
ent: "site*exec"; regex; nocase; flags: A+; reference:bugtraq,2241;
reference:arachnids
,317; classtype:bad-unknown; sid:361; rev:2;)
```

Finally, ftp access can be restricted by using TCP wrappers.

Multiple Choice Question

The * symbol can be used with the regex option when writing a Snort rule to specify a range of characters. What symbol can be used to represent a single wildcard character?

A) %
B) +
C) ?
D) $

The answer is C.

Detect 2 – ShellCode x86 NOOP

Alert

Event Name	Detect Time	Target Address	Target Port	Source Address	Source Port
SHELLCODE x86 NOOP	2/1/02 00:32:34 PST	Target.net.106.227	514	Attacker.net.12.107	58289

Source of Trace
This trace came from a network that I have access to.

Detect was generated by
These alerts were generated by snort version 1.8.3 running with the full rule set available at www.snort.org. I didn't have access to the alert file at the time this alert was generated so I pulled it out of the mysql database that snort also logs to. This alert was generated by the following snort rule.
alert ip $EXTERNAL_NET any -> $HOME_NET any (msg:"SHELLCODE x86 NOOP"; content: "|90 90 90 90 90 90 90 90 90 90 90 90 90 90|"; depth: 128; refer

ence:arachnids,181; classtype:shellcode-detect; sid:648; rev:4;)

I didn't see the string "90 90 90 90 90 90 90 90 90 90 90 90 90 90" in the payload of the packet that generated this alert because tcpdump wasn't logging the full payload. By default tcpdump only logs the first 68 bytes. In the future I will consider recommending increasing the snaplen but it will take up more storage space.
I didn't include the tcpdump output for this alert because I didn't have enough of the payload to make worthwhile. Basically what I saw were connection attempts to the targeted host on port 514 and the host responded with resets because it is not listening on the targeted port.

Probability the source address was spoofed
In this case the source address was probably not spoofed because the attacker is probably trying to execute commands on the target system that will allow him to gain access. In order for that to work he will need to complete the three way handshake which will not be possible if the source address is spoofed.

Description of the Attack
At first I thought this attack was targeted at the syslog port but if you recall syslog is UDP 514. In this case the attack is using the TCP protocol. After further research I discovered that there is an RPC Backdoor associated with TCP port 514. TCP port 514 is also associated with remote shell. I found this information using the ports database at www.snort.org
I did find a CVE reference to what may be the intent of this attack.
CAN-2001-0707
"** CANDIDATE (under review) ** Denicomp RSHD 2.18 and earlier allows a remote attacker to cause a denial of service (crash) via a long string to port 514."
http://cve.mitre.org/cgibin/cvekey.cgi?keyword=port+514
I do not believe this attack to have been successful because the targeted host was not listening on tcp 514 and sent a reset back to the attacker.

Attack Mechanism
This alert is triggering off the NOOP or no operation padding 9090 9090 bytes usually found in buffer overflows. Attackers use NOOPs to fill up the memory allocated to a certain application and when it fills up, the stack crashes and arbitrary code can be fed to the processor. In this case the attack is targeted at TCP port 514 so I researched vulnerabilities related to services that run on that port. There were not many references to exploits, especially buffer overflows, dealing with TCP port 514.
I would typically expect to see a payload similar to the following one where you can clearly see the padding and the shell code near the bottom of the payload. In this example the buffer overflow is attempting to execute /bin/sh after the stack is crashed.

The ports Database on www.Snort.org returned that the target port in this case is associated with an RPC backdoor but I didn't find any references to that on Google, Cert.org, or the SANS site.
I found the following information by searching Google and various other search engines.

I found that TCP rsh (remote shell) can send a command to a shell on the remote machine and receives the stderr and stdout from it. I also found the following explanation of a weakness in 4.2BSD.

> "4.2BSD provides a remote execution "server", which listens for TCP connection requests on port 514. When such a request arrives at a machine, the server checks that the originating host is "trusted" by comparing the source host ID in the IP header to a list of trusted computers. If the source host is OK, the server reads a user id and a command to execute from the virtual circuit TCP provides. The weakness in this scheme is that the source host itself fills in the IP source host id, and there is no provision in 4.2BSD or TCP/IP to discover the true origin of a packet."

I don't think that this is a valid explanation of what I have seen here. I have yet to find a buffer overflow related to the remote shell service.
I found the following warning on Xforce regarding rsh running on windows servers.

> "The Rsh service was detected as running. A version of rsh ships with the Windows NT Resource Kit, which executes all commands, regardless of user, under the system account. The system account is the most powerful account on a Windows NT computer, and we recommend not running this service under any circumstances. If this service is detected, use the instsrv tool, which also ships with the Windows NT Resource Kit, to remove the rsh service."
> http://www.iss.net/security_center/static/114.php

Correlations
I didn't find any correlations for traffic matching this alert. There are many references to the ShellCode x86 NOOP alert but not targeted at TCP port 514. Some of the references I found to the alert name are listed bellow.
http://lists.insecure.org/incidents/2001/Oct/0018.html

The traffic here clearly shows the padding in the payload of the packet. Some of the payload has been removed to save space.

```
44 24 18 2B F3 8B 08 03 CE 89 08 B8 01 00 00 00 D$.+............

00 EB 02 33 C0 85 C0 74 12 A3 B4 26 44 00 C7 05 ...3...t...&D...
```

Sans also had reports of similar traffic.

```
Feb  5 15:33:56 hostka snort[23477]: IDS362 - MISC - Shellcode X86
NOPS-UDP:
  207.238.5.67:733 -> a.b.c.225:32772
```

http://www.sans.org/y2k/020901-1200.htm

Evidence of active Targeting
I can't tell if this was active targeting or part of a random attack. The targeted server was not listening on tcp port 514 or UDP port 514 so if this were active targeting it wouldn't make much sense.

Severity
Criticality = 5 This server is a part of the network infrastructure for target.net and is required for business purposes.

Lethality = 3 since this attack did not allow access to the system and at most could crash the rshell service I wouldn't consider this attack to be extremely lethal.

System Countermeasures = 5 This host was not listening on the targeted port therefore the attack could not have been successful.

Network Countermeasure = 1 This server is in the DMZ and is allowed to be accessed from the internet. There are no ACL's in place or rules on the firewall that would prevent this attack.

(Criticality + Lethality) –
(System Countermeasures + Network Countermeasures) = Severity

(5 + 3) – (5 + 1) = 2

Defensive Recommendations
I would recommend blocking access to port 514 at the perimeter firewall. Port 514 is associated with remote shell which will allow trusted IP's to execute commands on the

host running that service. Someone could spoof a trusted IP have access to that host. If this host were running the rshell service I would recommend turning it off. I would also recommend blocking all unnecessary ports at the firewall to help protect hosts on the internal and DMZ networks. The best way to do this is have a deny al rule and then allow only the necessary ports to be open.

Multiple Choice Question

Syslogd runs on UDP/514 what service typically runs on TCP/514
A) krshd
B) rshell
C) The tcp implementation of syslogd
D) Secure Syslog

The answer is B rshell or remote shell.

Detect 3 – RPC EXPLOIT statdx

Source of Trace
This trace came from a network that I have access to.

Detect was generated by
These alerts were generated by snort version 1.8.3 running with the full rule set available at www.snort.org. This alert was generated by the following snort rule.

```
alert tcp $EXTERNAL_NET any -> $HOME_NET any (msg:"RPC EXPLOIT statdx";
flags: A+; content: "/bin|c74604|/sh";reference:arachnids,442;
classtype:attempted-admin; sid:600; rev:1;)
```

I didn't see the string `"/bin|c74604|/sh"` in the payload of the packet that generated this alert because tcpdump wasn't logging the full payload. By default tcpdump only logs the first 68 bytes. In the future I will consider recommending increasing the snaplen but it will take up more storage space.
The raw packet data was gathered from a host outside the firewall running tcpdump and logging to a repository. I grabbed the tcpdump output after I found these alerts and wrote several filters and then loaded that into ethereal and saved the output to a text file because it is easier to read.

Probability the source address was spoofed
I don't believe that the source addresses were spoofed because in order for this attack to be successful a three-way handshake must take place. The attacker is also looking to gain access to the system which would be impossible if he spoofed his source address.

Description of attack
The target of this attack was running a version of Linux called Slackware version 8. I do not believe that it is vulnerable to this exploit. In this case at least it did not appear that the attack was successful. The RPC statd exploit is a very common exploit and has even been used as part of larger worms and Trojans such as the Ramen worm that would deface websites with a picture of Ramen Noodles. It targets a known vulnerability in an RPC daemon called StatD. The purpose of statd is to implement the Network Status Monitor RPC protocol to provide reboot notification for other services such as the NFS service. This exploit was reported to Bugtraq on August 5, 2000, so it is now almost 2 years old. The CVE reference for this exploit is located at the following link.
http://www.cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0666

CVE states, “rpc.statd in the nfs-utils package in various Linux distributions does not properly cleanse untrusted format strings, which allows remote attackers to gain root privileges”

Attack Mechanism

One of the processes associated with rpc.statd passes logging information using the syslog() function. The format string that is passed is user supplied data and there is no bounds checking. Since there is no bounds checking this buffer can be overflowed, which in turn would place executable code into the process address space and overwrite the process return address, forcing the execution of what could and typically is malicious code.

As I stated earlier the packet that I collected that triggered this alert didn’t contain enough of the payload for me to show exactly what was happening. A friend of mine had a similar trace and he didn’t have the same storage restrictions that I have therefore he was able to retain the entire packet. I have included that here.

```

If you look at the sections of the payload that have been bolded you will see that the beginning of the payload is very similar to the packet I received. Near the end of the payload you will see bin/sh. If you notice the 9090 bytes, those are used to fill up the buffer. In other words those bytes do nothing but fill up the buffer so that the stack can be smashed and the malicious code i.e. bin/sh, can be executed. 9090 represents a NOOP or

a no operation, it indicates no operation to be executed. This means that they are not instructing the processor to do anything.

Correlations
I found many correlations for traffic similar to this. Once this exploit was posted to Bugtraq there were increased scans looking for systems with port 111 or rpcinfo listening so the attacker could find out what port statd was running on.
Laurie Zirkle reported the following traffic to incidents.org

```
Dec  6 05:21:36 hosty snort: [ID 702911 local0.alert] [1:583:2] RPC
portmap request rstatd [Classification: Decode of an RPC Query]
[Priority: 2]: {UDP} 194.251.105.187:854 -> z.y.x.34:111

http://www.incidents.org/archives/intrusions/msg02909.html

Evidence of Active targeting
This alert shows many signs of active targeting. I say this because after looking into my snort logs for other events from this source address or targeted at this destination address I found the following alerts.

```
[**] [1:596:2] RPC portmap listing [**]
[Classification: Decode of an RPC Query] [Priority: 2]
01/27-20:55:24.312486 attacker.net.99.232:939 -> target.net.233.44:111
TCP TTL:46 TOS:0x0 ID:42709 IpLen:20 DgmLen:96 DF
***AP*** Seq: 0xD00567AF  Ack: 0x51C032C3  Win: 0x16D0  TcpLen: 32
TCP Options (3) => NOP NOP TS: 4112884 1684510
[Xref => http://www.whitehats.com/info/IDS429]
```

This alert shows the attacker requesting rpc port map info on my host. He would have done this in order to find out what port the rpc.statd service was running on. Then an hour later he decided to run a statd buffer flow targeted at a host he knew was running the exploitable service.

Severity
Criticality = 5 This server is a part of the network infrastructure for target.net and is required for business purposes.

Lethality = 5 Any attack that gives an attacker root on one of my network devices is considered to be extremely lethal.

System Countermeasures = 5 The version of Slackware that was running on the target of this attack is not vulnerable to this exploit.

Network Countermeasure = 1 This server is in the DMZ and is allowed to be accessed from the internet. There are no ACL's in place or rules on the firewall that would prevent this attack.

(Criticality + Lethality) –
(System Countermeasures + Network Countermeasures) = Severity

(5 + 5) – (5 + 1) = 4

Defensive Recommendations
I would recommend not running rpc services on hosts that are accessible from the Internet. Since portmapper-managed ports are dynamically assigned, it is difficult to firewall individual ports and may be more feasible to "deny all unless specifically allowed", at least on ports less than 1024. I would also recommend that any servers running rpc services are using a version that is not vulnerable to rpc exploits. I would like to refer you to an excellent paper that describes the uses, the dangers, and how to protect your self from vulnerabilities related to RPC. I would recommend implementing the suggestions made in the What To Do section of this paper.
http://www.sans.org/newlook/resources/IDFAQ/blocking.htm

Multiple Choice Question
What is the default snaplen of TCPDUMP?
A) 48

B) 72
C) 32
D) 68

The answer is D. 68 "`Snarf snaplen bytes of data from each packet rather` than the default of 68" http://www.tcpdump.org/tcpdump_man.html

Detect 4 – EXPLOIT LPRng overflow

Alert

Event Name	Protocol	Detect Time	Target Address	Target Port	Source Address	Source Port
EXPLOIT LPRng overflow	TCP	1/29/02 23:58:43 PST	target.net.106.217	515	Attacker.net.12.33	50418

Source of Trace
This trace came from a network that I have access to.

Detect was generated by
These alerts were generated by snort version 1.8.3 running with the full rule set available at www.snort.org. This alert was generated by the following snort rule.

```
alert tcp $EXTERNAL_NET any -> $HOME_NET 515 (msg:"EXPLOIT LPRng o
verflow"; flags: A+; content: "|43 07 89 5B 08 8D 4B 08 89 43 0C B0 0B
CD 80 31 C0 FE C0 CD 80 E8 94 FF FF FF 2F 62 69 6E 2F 73 68 0A|";
reference:bugtraq,1712;
 classtype:attempted-admin; sid:301; rev:1;)
```

I didn't include the tcpdump output for this alert because I didn't have enough of the payload to make worthwhile. Basically what I saw were connection attempts to the targeted host on port 515 and the host responded with resets because it was not listening on the targeted port.

Probability the source address was spoofed
I don't believe that the source addresses were spoofed the packets contained no signs of spoofing. A blind spoof would defeat the purpose of this attack.

Description of attack
This attack is looking to exploit a vulnerability found in the LPrng service of some Linux distributions. The LPrng service is a printer daemon that runs on port 515 TCP/UDP. LPRng is a print spooling system that was designed to mimic the BSD line printer service. LPrng will print a document with little or no knowledge of its contents and no special processing is required to print on a local machine or in a distributed printing environment. Within the code there is a format string vulnerability that could allow an attacker to execute arbitrary code.
The CVE reference is listed bellow.

CVE-2000-0917 "Format string vulnerability in use_syslog() function in LPRng 3.6.24 allows remote attackers to execute arbitrary commands." http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0917

Attack Mechanism

According to The cert advisory http://www.kb.cert.org/vuls/id/382365 LPrng

> "has a missing format string argument in at least two calls to the syslog() function. Missing format strings in function calls which allow user-supplied arguments to be passed to a susceptible *snprintf() function call may allow remote users with access to the printer port (port 515/tcp) to pass format-string parameters that can overwrite arbitrary addresses in the printing service's address space. Such overwriting can cause segmentation violations leading to denial of printing services or lead to the execution of arbitrary code injected through other means into the memory segments of the printer service."

The attack mechanism is a classic buffer overflow exploit. This attack works by sending packets padded with NOOPs in order to "smash the stack" or overflow the memory buffer. Once the buffer is overflowed, /bin/sh is passed to the processor and executed as if it were part of the LPrng service. There is sample code available from http://www.rdcrew.com.ar/files/rdC-LPRng.c If we examine a snip of the exploit we will see the use of shell code.

```
char shellcode[]= // not
mine"\x31\xc0\x31\xdb\x31\xc9\xb3\x07\xeb\x67\x5f\x8d\
x4f"
"\x07\x8d\x51\x0c\x89\x51\x04\x8d\x51\x1c\x89\x51\x08"
"\x89\x41\x1c\x31\xd2\x89\x11\x31\xc0\xc6\x41\x1c\x10"
"\xb0\x66\xcd\x80\xfe\xc0\x80\x79\x0c\x02\x75\x04\x3c"
"\x01\x74\x0d\xfe\xc2\x80\xfa\x01\x7d\xe1\x31\xc0\xfe"
"\xc0\xcd\x80\x89\xd3\x31\xc9\x31\xc0\xb0\x3f\xcd\x80"
"\xfe\xc1\x80\xf9\x03\x75\xf3\x89\xfb\x31\xc0\x31\xd2"
"\x88\x43\x07\x89\x5b\x08\x8d\x4b\x08\x89\x43\x0c\xb0"
"\x0b\xcd\x80\x31\xc0\xfe\xc0\xcd\x80\xe8\x94\xff\xff"
"\xff\x2f\x62\x69\x6e\x2f\x73\x68";
```

The following piece of code is where the vulnerability lies in LPrng.

```
LPRng-3.6.24/src/common/errormsg.c, use_syslog()
---
static void use_syslog(int kind, char *msg)
[...]
# ifdef HAVE_OPENLOG
        /* use the openlog facility */
        openlog(Name, LOG_PID | LOG_NOWAIT, SYSLOG_FACILITY );
        syslog(kind, msg);
        closelog();

# else
    (void) syslog(SYSLOG_FACILITY | kind, msg);
# endif                                                  /*
```

```
HAVE_OPENLOG */
[...]
```

There is also an excellent article which discuses this vulnerability on the SANS site. http://rr.sans.org/malicious/ramen.php The paper is discussing the Ramen worm but it discusses this vulnerability as well since it is one of the vulnerabilities Ramen looks to exploit.

Correlations

Kathy Bergsma reported scans for port 515 to insecure.org at the handler notes are available at the following link.
http://lists.insecure.org/incidents/2000/Dec/0006.html

Some Port 515 activity can be attributed to the Ramen worm as described by Matt Fearnow at the following SANS link. The Ramen worm will try to exploit remote systems using this LPrng vulnerability.
http://www.sans.org/y2k/012201.htm

Evidence of Active Targeting

If this host were running LPrng printer services I would think that this would be an example of active targeting. In this case the server was not and therefore I wouldn't expect this exploit to be targeted at this host. I have also never seen any activity from the source address of this attack targeted at target.net. If an attacker had scanned the network before they would have known that this server was not running LPrng and would probably not have chosen this as an attack method.

Defensive Recommendations

First off I would recommend not allowing access to internal servers from the Internet. I don't believe that there is any reason that would justify having port 515 accessible from the net even though this box is in the DMZ. If this server were running LPrng services I would recommend upgrading to version 3.6.24-2 or later for RedHat. There is a complete list for other operating systems at the following link. http://www.cert.org/advisories/CA-2000-22.html

Severity

Criticality = 5 This server is a part of the network infrastructure for target.net and is required for business purposes.

Lethality = 5 Any attack that could potentially give an attacker root is considered to be extremely lethal.

System Countermeasures = 5 LPrng was not running on the targeted system.

Network Countermeasure = 1 This server is in the DMZ and is allowed to be accessed from the internet. There are no ACL's in place or rules on the firewall that would prevent this attack.

(Criticality + Lethality) –

(System Countermeasures + Network Countermeasures) = Severity

(5 + 5) – (5 + 1) = 4

Multiple Choice Question
The following logs showing a scan for the LPrng port were generated by?

```
Jan 29 17:50:54 host1 snort: [1:0:0] TCP to 515 lpr {TCP}
 X.X.186.238:1837 -> X.X.140.157:515
Jan 29 17:50:54 host1 snort: [1:0:0] TCP to 515 lpr {TCP}
 X.X.186.238:1837 -> X.X.140.157:515
```

A) IP Tables
B) TcpDump
C) Gauntlet
D) IP Chains

The answer id D. IP Chains

```

The following logs were found in /var/log/messages of the attacked host. Note the time difference is because the system clocks were not in sync. NTP would be very useful for this purpose because when doing analysis detect times are very critical.

Source of Trace
This trace came from a network that I have access to.

Detect was generated by
These alerts were generated by snort version 1.8.3 running with the full rule set available at www.snort.org. This alert was generated by the following snort rule.

```
alert tcp $EXTERNAL_NET any -> $HOME_NET 22 (msg:"EXPLOIT ssh CRC3
2 overflow"; flags:A+; content:"|00 01 57 00 00 00 18|"; offset:0;
depth:7; cont
ent:"|FF FF FF FF 00 00|"; offset:8; depth:14; reference:bugtraq,2347;
reference
:cve,CVE-2001-0144; classtype:shellcode-detect; sid:1327; rev:1;)
```

The raw packet data was gathered from a host outside the firewall running tcpdump and logging to a repository. I grabbed the tcpdump output after I found these alerts and wrote several filters and then loaded that into ethereal and saved the output to a text file because it is easier to read.

Probability the source address was spoofed
I don't believe that the source addresses were spoofed because in order for this attack to be successful a three-way handshake must take place. Another reason the source address is most likely not spoofed is that the attacker is attempting to issue commands on the system that will allow him access. An ideal command would be bin/sh that could enable the attacker to gain a remote shell. If he spoofed his source address the shell would never be returned to him.

Attack Description
This attack was target at a sever in the DMZ that was running a vulnerable version of SSH. I believe that this attack may have been successful because of the messages I saw in /var/messages. The following cert advisory states, "In reports received by the CERT/CC, systems compromised via this vulnerability have exhibited the following pattern in system log messages:

```
hostname sshd[xxx]: Disconnecting: Corrupted check bytes on
input.
hostname sshd[xxx]: Disconnecting: crc32 compensation attack:
network attack detected
hostname sshd[xxx]: Disconnecting: crc32 compensation attack:
network attack detected"
```
http://www.cert.org/advisories/CA-2001-35.html

These logs look very similar to the logs I found on my host.

```
Jan 21 15:44:20 Natasha sshd[2699]: Disconnecting: Corrupted
check bytes on input.
Jan 21 15:46:26 Natasha sshd[2700]: Disconnecting: Corrupted
check bytes on input.
Jan 21 16:39:42 Natasha sshd[565]: Generating new 768 bit RSA
key.
Jan 21 16:39:43 Natasha sshd[565]: RSA key generation complete.
Jan 21 16:40:34 Natasha sshd[2882]: Disconnecting: crc32
compensation attack: network attack detected
      Jan 21 16:41:05 Natasha sshd[2883]: Disconnecting: crc32
      compensation
```

The CVE reference for this vulnerability is CVE-2001-0144 and is available at http://cve.mitre.org/cgi-bin/cvekey.cgi?keyword=EXPLOIT+ssh+CRC32+overflow+ CVE states "CORE SDI SSH1 CRC-32 compensation attack detector allows remote attackers to execute arbitrary commands on an SSH server or client via an integer overflow."

Attack Mechanism

SSH is a widely used client-server application for authentication and encryption of network communications it is a more secure replacement for applications such as telnet and rlogin. In 1998 a design flaw in the SSH1 protocol was discovered that could lead an attacker to inject malicious packets into an SSH encrypted stream that would allow execution of arbitrary commands on either client or server. They couldn't fix the problem with out breaking the protocol so they introduced a way to detect the attack. They introduced a file called deattack.c but a vulnerability existed in this file.

> "There is a remote integer overflow vulnerability in several implementations of the SSH1 protocol. This vulnerability is located in a segment of code that was introduced to defend against exploitation of CRC32 weaknesses in the SSH1 protocol (see VU#13877). The attack detection function (detect_attack, located in deattack.c) makes use of a dynamically allocated hash table to store connection information that is then examined to detect and respond to CRC32 attacks. By sending a crafted SSH1 packet to an affected host, an attacker can cause the SSH daemon to create a hash table with a size of zero. When the detection function then attempts to hash values into the null-sized hash table, these values can be used to modify the return address of the function call, thus causing the program to execute arbitrary code with the privileges of the SSH daemon, typically root."
>
> This description of the SSH vulnerability is from the cert advisory located at the following link. http://www.kb.cert.org/vuls/id/945216

There is a great description of this vulnerability and a walk through of the vulnerable code located at the following link.
http://www.securiteam.com/securitynews/5LP042K3FY.html
I would also recommend visiting the security focus archive that also gives a good description of the vulnerable code.
http://www.securityfocus.com/archive/1/161444

Correlations
The following traffic was reported to Vicki Iriwin who was the handler on duty at Incidents.org. They received many alerts in their logs for port 22 which is associated with SSH. http://www.incidents.org/diary/november01/111201.php

```
Nov  1 18:47:47 victim sshd[9531]: log: Connection from 10.10.10.10
port 33318
Nov  1 18:47:47 victim sshd[9532]: log: Connection from 10.10.10.10
port 33319
Nov  1 18:47:48 victim sshd[9533]: log: Connection from 10.10.10.10
port 33320
Nov  1 18:47:48 victim sshd[9534]: log: Connection from 10.10.10.10
port 33321
Nov  1 18:47:48 victim sshd[9535]: log: Connection from 10.10.10.10
port 33322
Nov  1 18:47:49 victim sshd[9536]: log: Connection from 10.10.10.10

You may also want to look at the following link containing a write up this attack by Dave Dittrich. dittrich@cac.washington.edu
http://lists.bikkel.org/archive/whitehat/Week-of-Mon-20011105/000215.html

Evidence of Active Targeting
This was more that likely active targeting. The fact that the attacker knew that particular server was running SSH was not a coincidence. They used an SSH exploit which infers that they knew the host was running SSH and that the host was accessible. I would like to go back and review the scan logs to see if any scans came from this attacker prior to the attack. A scan originating from this attacker in the weeks prior would be concrete evidence of active targeting.

Severity
Criticality = 4 This server is used as part of the business infrastructure and causes many interruptions when it is down. It is not a mail server or DNS, but from this system an attacker may be able to access other systems with information he could gather.

Lethality = 5 Any attack that gives an attacker root on one of my network devices is considered to be extremely lethal.

System Countermeasures = 0 The targeted host was running a version of OpenSSH prior to version 2.3.0 where the problem was addressed.

Network Countermeasure = 0 This server is in the DMZ and is allowed to be accessed from the internet. There are no ACL's in place or rules on the firewall that would prevent this attack.

(Criticality + Lethality) –
(System Countermeasures + Network Countermeasures) = Severity

(4 + 5) – (0 + 0) = 9

Defensive Recommendations
First off I will recommend rebuilding this server and wiping the disks. If the attacker gained root access to the system there is no telling what sort of Trojan, or rootkit software he may have downloaded and installed. With out a program such as tripwire it is extremely difficult to track down system modifications. Installing Tripwire is a must. www.tripwire.org
Any box that has been compromised should be rebuilt. I would recommend that upon rebuilding the server that the version of SSH is greater than 2.3. Open ssh is available at http://www.openssh.com Furthermore hardening of the firewall would be in order. Since SSH into this server is a necessity considerations should be made as to which IP addresses or groups of IP addresses are allowed to access it and be enforced on the firewall using access controls. For future network design decisions I would remove the necessity of SSH in the DMZ. If access to the DMZ is necessary from offsite I would recommend the use of a VPN device which supports authentication and encryption.

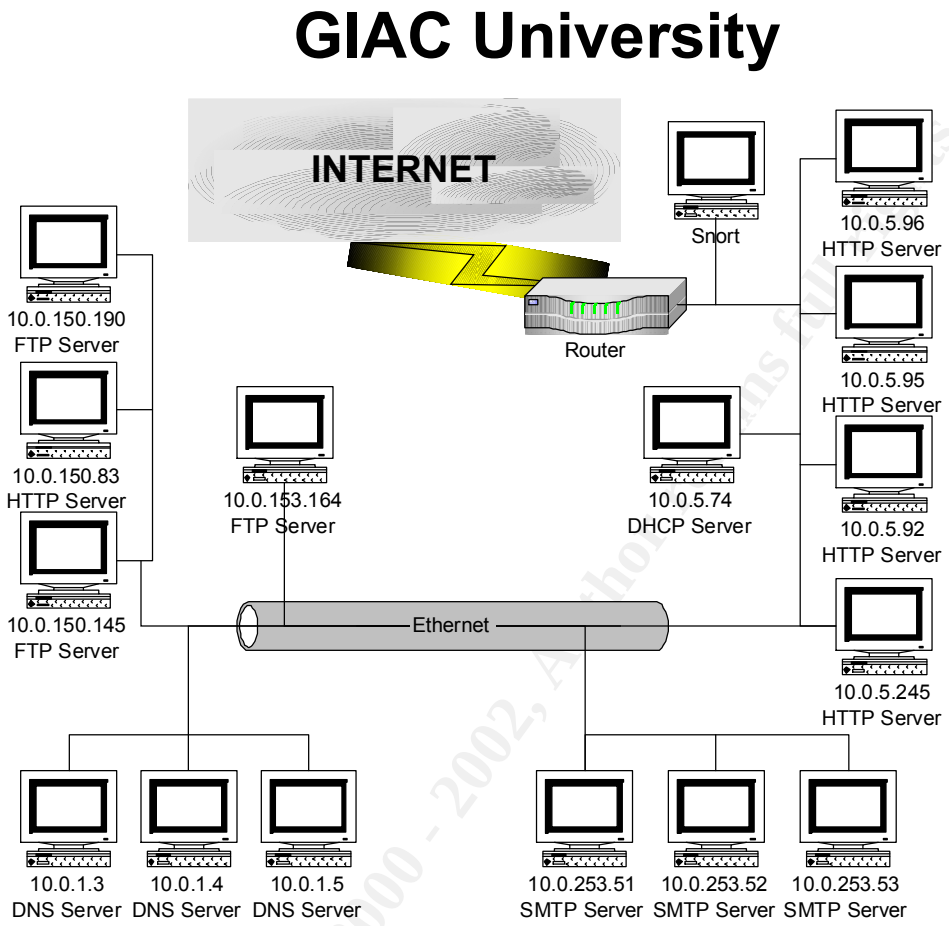
Multiple Choice Question
Buffer overflows fill up memory with NOOPS (no operation), which causes the stack to crash and allows for the execution of arbitrary code. Which of the following strings would you look for in a snort rule to find packets with NOOP's?

A) %F
B) %%
C) 90
D) 09

The answer is c 90.
You will often see packets filled with "90" which may indicate padding for a buffer flow attack.
See the following snort rule for an example of how you could detect NOOP's in a packet.

alert tcp $NET any -> $MY_NET any (msg:"**Possible BufferFlow NOOPs FOUND**"; flags:A+; content:"|90 90 90 90 90 90 90 90 90 90 90 90 90 90 90 90 90 90|";

Assignment 3 "Analyze This"



This is the assumed topology of the GIAC University Network. All assumptions here were based on traffic that was seen in the supplied Alert, Scan, and OOS data files. If there are services that I have represented here which are actually not running on these servers than further investigation is necessary.

Executive Summary

I have been hired to conduct a security audit for the GIAC University Network. I was supplied with five days worth of data ranging from Snort Alerts to Scan Logs and OOS events. The date range I analyzed was from 1-4-02 through 1-8-02. I received the following files:

Snort Alert	OOS	SCAN
alert.020104.gz	oos_Jan.4.2002.gz	scans.020104.gz
alert.020105.gz	oos_Jan.5.2002.gz	scans.020105.gz
alert.020106.gz	oos_Jan.6.2002.gz	scans.020106.gz
alert.020107.gz	oos_Jan.7.2002.gz	scans.020107.gz
alert.020108.gz	oos_Jan.8.2002.gz	scans.020108.gz

For this analysis I have converted all the MY.NET addresses to the 10.0. address space. I needed to do this conversion for my queries and reports to work properly. From this point

on I will not reference MY.NET and all references will be made to 10.0.X.X addresses. Included in my report you will find analysis of the top 20 alerts reported for the specified time range, including a description of each and defensive recommendations. You will also find a top talkers summary for each of the data sets along with who is information for those hosts. In the last section I have included a link graph that displays all traffic to and from a host that I believe to have been compromised. I have also indicated through out the report any hosts that I feel should be investigated further to confirm whether or not they have been compromised.

Alert Summary

This Report represents the Unique Alerts that were reported from snort. I have excluded the Scans and the ICMP traffic that I didn't find to be an indication of any compromised system. Following this report I have included a description of the top 20 alerts and defensive recommendations for each. Followed by any external correlations I could find on either the external source or target addresses.

Connect to 515 from Inside

Event Name	count of Event Name	Distinct SRC	Distinct TGT
Connect to 515 from inside	19538	38	2

➢ **Brief Alert Description**

Port 515 is LPRng service which is basically a printer service. There have been several vulnerabilities published which target particular versions of this service. The vulnerability is explained in the following quote from a SANS security advisory. "The vulnerability is due to incorrect usage of the syslog (3) function. Local and remote users can send string-formatting operators to the printer daemon to corrupt the daemon's execution, potentially gaining root access."
http://www.sans.org/newlook/alerts/port515.htm
Since port 515 is potentially vulnerable I decided to look at the distinct sources from which this event was triggered. They are listed bellow.

Distinct Sources

10.0.152.166	10.0.153.120	10.0.153.154	10.0.153.195
10.0.152.167	10.0.153.121	10.0.153.163	10.0.153.209

10.0.152.170	10.0.153.122	10.0.153.164	10.0.253.10
10.0.152.182	10.0.153.125	10.0.153.165	10.0.88.148
10.0.153.106	10.0.153.126	10.0.153.172	10.0.88.181
10.0.153.108	10.0.153.127	10.0.153.173	10.0.153.119
10.0.153.109	10.0.153.137	10.0.153.174	10.0.153.150
10.0.153.114	10.0.153.146	10.0.153.178	10.0.153.193
10.0.153.115	10.0.153.148	10.0.153.186	
10.0.153.117	10.0.153.149	10.0.153.189	

Since all of these source addresses are internal GIAC university addresses I would assume that this traffic is legitimate network traffic and that the two target addresses 10.0.150.198 and 10.0.153.111 are actually running some sort of network printer services and this traffic should not be reason for alert.

- **Defensive Recommendations**

In this case I have made the assumption that the two servers that are targeted by this alert are running print services and this traffic should not be investigated further. I would however be suspicious if I saw external connections to either of these servers on port 515 so as to help ensure that these services are not accessible from the Internet, I would block that port at the perimeter firewall. As well as blocking this service from being accesses by external sources, I would ensure that the servers are up to the latest patch level and should run LPRng version 3.6.25 as a minimum.

- **Correlations**

Many sites have seen increased number of scans looking for port 515. These sites include the following:
http://www1.dshield.org/port_report.php?port=515
http://www.sans.org/newlook/alerts/port515.htm
Since none of the Source IP addresses were external I was unable to find any source IP address correlations.

spp_http_decode: IIS Unicode attack detected

Event Name	count of Event Name	Distinct SRC	Distinct TGT
spp_http_decode: IIS Unicode attack detected	17315	64	259

- **Brief Alert Description**

The IIS Unicode attack is an attack that targets windows servers running IIS web services, if successful this exploit allows attackers to execute commands by issuing crafted http queries. This exploit grew from an older exploit called dot dot, which allowed for directory traversal by the attacker. The Unicode vulnerability is exploited by substituting a standard "/" with the Unicode translation which is "\" The following quote is from the Xforce advisory regarding IIS Unicode attacks. "By appending the '..' and a Unicode slash or backslash after a virtual directory with execute permissions, it is possible for an attacker to execute arbitrary commands."
http://xforce.iss.net/alerts/advise68.php

Since this is a potentially serious vulnerability I decided it requires further investigation. Bellow are the internal target IP's. I am not concerned with target addresses that are external because some normal web traffic has been mistaken as Unicode alerts in the past.
http://www.securityfocus.com/archive/96/183184

Target IP's in GIAC University
10.0.11.4
10.0.150.83
10.0.5.245
10.0.5.92
10.0.5.95
10.0.5.96

I examined the traffic originating from these IP addresses to see if there was any indication that the Unicode attacks were successful and I found the following:

10.0.11.4
Traffic originating from this IP address was all reported as scans there were 70 events in the scans logs showing what appeared to be FTP traffic since all the records contained source port 20. I would be concerned about this traffic but all the addresses were internal which leads me to believe that this server runs FTP services. Other traffic targeted at this IP address all seemed to be normal network traffic that was reported as scans from internal sources. The only alert from an external source was the Unicode attack. I would consider this to be a false alert.

10.0.150.83, 10.0.5.245, 10.0.5.92, 10.0.5.95, 10.0.5.96
I believe these addresses to be web servers, as indicated in the network topology at the beginning of this section. They should be treated as a high risk and critical servers. I looked through the supplied data and there were no alerts, scans, or OOS events originating from these IP addresses which indicates that they were most likely not compromised. Although they were all targets of several other web exploits, the only server that was targeted by this exploit from an external source was 10.0.5.245. On Jan 5th at 10:56 there were 6 attempts from the same source address to this web server.

Detect Time	Event Name	Source Address	Target Address
5 Jan 2001 10:56:10 PST	spp_http_decode: IIS Unicode attack detected	211.93.8.74	10.0.5.245
5 Jan 2001 10:56:08 PST	spp_http_decode: IIS Unicode attack detected	211.93.8.74	10.0.5.245
5 Jan 2001 10:56:08 PST	spp_http_decode: IIS Unicode attack detected	211.93.8.74	10.0.5.245
5 Jan 2001 10:56:07 PST	spp_http_decode: IIS Unicode attack detected	211.93.8.74	10.0.5.245
5 Jan 2001 10:56:07 PST	spp_http_decode: IIS Unicode attack detected	211.93.8.74	10.0.5.245
5 Jan 2001 10:56:07 PST	spp_http_decode: IIS Unicode attack detected	211.93.8.74	10.0.5.245

Following is the ARIN whois information regarding this source address
Results:
Asia Pacific Network Information Center (NETBLK-APNIC-CIDR-BLK)
These addresses have been further assigned to Asia-Pacific users.
Contact info can be found in the APNIC database,

Coordinator:
Administrator, System (SA90-ARIN) [No mailbox]
+61-7-3367-0490

Domain System inverse mapping provided by:

NS.APNIC.NET	203.37.255.97
SVC00.APNIC.NET	202.12.28.131
NS.TELSTRA.NET	203.50.0.137
NS.RIPE.NET	193.0.0.193

- **Defensive Recommendations**

Since these systems all appear to be web servers you cannot block port 80 access to them. If these servers were running IIS I would ensure that they are up to the latest patch release from Microsoft. If they are not running IIS than I would not worry about this exploit since it only targets vulnerabilities found in IIS servers. As for the source address 211.93.8.74 unless there is a legitimate reason for this traffic I would consider blocking this IP address from accessing internal servers. Further investigation would be required.

- **Correlations**

I found no correlations for this external source IP on Incidents.org, Google, or on the SANS site.

SNMP public access

Event Name	count of Event Name	Distinct SRC	Distinct TGT
SNMP public access	11554	14	136

- **Brief Alert Description**

Simple Network Management Protocol (SNMP), is used by administrators to monitor various network devices. This alert confirms the use of SNMP, which is considered to be a security risk especially if you are using a public community string. SNMP uses no authentication and is not encrypted. The only authentication is the use of a community string that is usually set to public by most vendors. SNMP poses several vulnerabilities according to The Top Ten vulnerabilities published by SANS. "Attackers can use this vulnerability in SNMP to reconfigure or shut down devices remotely. Sniffed SNMP traffic can reveal a great deal about the structure of your network, as well as the systems

and devices attached to it. Intruders use such information to pick targets and plan attacks." http://www.sans.org/topten.htm

➢ **Defensive Recommendations**

Unless SNMP is necessary and justified I would suggest not using SNMP and would disable it wherever possible. If you require the use of SNMP you may want to take several steps to secure it as much as possible. First make the MIBS read only so that they cannot be modified. Additional information on this can be obtained from http://www.cisco.com/univercd/cc/td/doc/cisintwk/ito_doc/snmp.htm#xtocid210315 Another step that should be considered would be to change the default community name to something that an attacker wouldn't be able to guess as easily.

➢ **Correlations**

Since these were all internal to internal addresses I could find no external correlations for the source addresses.

MISC Large UDP Packet

Event Name	Count of Event Name	Distinct SRC	Distinct TGT
MISC Large UDP Packet	8660	9	7

➢ **Brief Alert Description**

This alert is triggering off a UDP datagram larger than 4000 bytes. These alerts would have been triggered by a snort rule that looks like this.

```
alert udp $EXTERNAL_NET any -> $HOME_NET any (msg:"MISC Large UDP
Packet"; dsize: >4000; reference:arachnids,247; classtype:bad-unknown;
sid:521; rev:1;)
```

Source Address	Count of Source Address	Target Address	Count of Target Address
203.248.242.22	1897	10.0.153.154	2323
210.76.63.49	1519	10.0.88.167	1897
211.233.70.161	1263	10.0.88.165	1519
211.233.70.162	1060	10.0.153.210	969
203.199.69.118	969	10.0.153.45	941
202.102.29.141	593	10.0.150.143	593
216.106.166.211	476	10.0.153.118	418
216.106.166.164	465		
211.43.209.7	418		

While investigating these alerts further I believe that I have found several compromised hosts. I was looking at the traffic targeted at 10.0.153.154 and I saw external hosts accessing that server on port 7000 from source port 7001. These ports are associated with the Andrew File System or AFS. AFS is a distributed file system that was created at Carnegie Mellon University. The following link has a great deal of information on AFS. http://www.alw.nih.gov/Docs/AFS/AFS_toc.html What alarmed me was that the sources

were external which means that external hosts were accessing internal file systems. I decided to look into any other traffic that meets that criteria and I believe I have a list of 16 GIAC University hosts that are compromised. The hosts are

10.0.150.120
10.0.150.145
10.0.150.49
10.0.151.125
10.0.153.118
10.0.153.151
10.0.153.152
10.0.153.154
10.0.153.184
10.0.153.185
10.0.153.210
10.0.153.211
10.0.153.46
10.0.88.165
10.0.88.167
10.0.88.244

The following Alert and scan traffic is a small subset of all the traffic I saw like this.

Scan	UDP	7 Jan 2002 18:36:44 PST 10.0.88.165	7001 4.19.71.20	7000
Scan	UDP	4 Jan 2002 16:50:55 PST 10.0.88.167	7001 203.248.242.22	7000

I am most concerned with the Asian pacific addresses that are accessing GIAC University. The other traffic is all originating from large service providers like Level 3 and Qwest. The internal hosts that the traffic originating from the Asian Pacific address space is displayed bellow and the target hosts should be examined very carefully.

INFO - ICQ Access

Event Name	count of Event Name	Distinct SRC	Distinct TGT
INFO - ICQ Access	1910	2	42

- **Brief Alert Description**

ICQ is an application used by messenger like programs that basically informs you when other users are online. As stated on ICQ.com "With ICQ, you can chat, send messages, files and URL's, play games, or just hang out with your fellow 'Netters' while still surfing the Net." So is this a problem? Well it depends. Cert advisory CA-2002-02 claims that there are several ICQ buffer overflows that allow an attacker to execute arbitrary commands on the compromised system. http://www.cert.org/advisories/CA-2002-02.html In this case the ICQ alerts originate from only two IP addresses in the GIAC university network. They are 10.0.151.79 and 10.0.5.239. I felt that further investigation was

necessary into these source addresses to determine if they were compromised or just chatting on the net.
After looking at all events originating from these two sources it is most likely that these are users who are accessing chat rooms and using internet services such as IRC and AOL messenger. Depending on GIAC University security policies this may require further investigation.

- **Defensive Recommendations**

Again defensive recommendations are dependent upon policy in this case. If users are allowed to access Internet chat rooms and service such ads ICQ then there are no defensive recommendations that need to be made. Although the policy makers may want to take into consideration that there are known exploits associated with the applications that use ICQ. If the security policy that's in place prohibits users from accessing such services then it may be a good idea to block the ports associated with these services at the perimeter firewall.

- **Correlations**

I found no Correlations for the external source addresses on Google, SANS, or Incidents.org.

INFO MSN IM Chat data

Event Name	count of Event Name	Distinct SRC	Distinct TGT
INFO MSN IM Chat data	1827	47	49

- **Brief Alert Description**

This alert is detecting the traffic associated with Instant Messenger by Microsoft. Instant messenger is used much the same as an ICQ based service like AOL Instant messenger. I would not consider these alerts to require further investigation but there are known exploits that can allow a hacker to execute arbitrary commands on the target host. I also found a virus which propagates via MSN messenger services. http://www.zdnet.com/products/stories/reviews/0,4161,2769395,00.html I would however for security reasons not allow instant messenger connections to external sources. Sometimes a messenger like service can be useful within a company for employees to communicate back and forth or in this case students at GIAC University may use IM to chat with fellow students, but I would make a recommendation that this be disallowed by the security policy of the university.

- **Defensive Recommendations**

If Instant messenger is not allowed by the security policy than the recommendation I can suggest would be to block the ports associated with IM at the perimeter firewall. The usual ports that IM uses are TCP High Ports. Just by allowing TCP High Port traffic in to your internal network opens you up for all kinds of other vulnerabilities where attackers may come into your network on these open ports. It is good practice to not allow any services into your network that are not specifically stated in the security policy and a true necessity for the operations of your organization.

➢ **Correlations**

I found no correlations for these external source addresses on Incidents.org, Google, or the SANS site.

High port 65535 udp - possible Red Worm - traffic

10.0.153.204	33
10.0.153.211	30

➢ **Brief Alert Description**

The Red Worm now known as the Adore Worm is similar to the Ramen or Lion worms. What this worm does is scan Linux hosts on the Internet looking to see if the are susceptible to several vulnerabilities. The checks it makes are to see if the following services are running LPRng, Wu-Ftpd, rpc-statd and Bind. Once the worm finds an vulnerable system it exploits it using one of the previously listed vulnerabilities and it then Trojans the `ps` binary and moves the original to `/usr/bin/adore`. It then attempts to send various system information including /etc/ftpusers, ifconfig output, ps -aux (using the original binary in /usr/bin/adore), /root/.bash_history, /etc/hosts, and /etc/shadow. There is a detailed explanation of this worm on the SANS site at http://www.sans.org/y2k/adore.htm Another thing to take into account is that the code for this worm can be modified very easily so one should not assume that it will be listening on port 65535.

➢ **Defensive Recommendations**

There is a utility that is available from Dartmouth University written by William Stearns which will detect the adore files on an infected system. This utility is available at http://www.ists.dartmouth.edu/IRIA/knowledge_base/tools/adorefind.htm I would highly recommend that this tool be downloaded and run on all the hosts listed in the above tables. Another good recommendation would be to block emails to or from the following addresses adore9000@21cn.com, adore9000@sina.com, adore9001@21cn.com, adore9001@sina.com. The worm sends these email addresses your critical system information.

- **Correlations**

Since this potentially a very serious problem I felt that I should look further into traffic originating from the top internal targets and sources of this alert.

- **Internal Targets**

From the internal source address I found similar traffic from all of them that could indicate a code red infection. All the systems have traffic originating from them which could be the execution of a SYN scan of external hosts to see if they are listening on port 80. It could also just be a user on that system browsing the Internet. Either way I believe these hosts should be checked using the Adore Trojan utility from the link in defensive recommendations. The traffic bellow is from one such system. Some traffic has been removed due to the volume.

- **Internal Sources**

None of the internal targets of this alert made any connections to an external address which leads me to believe that they are most likely not compromised. Although I did find some very interesting traffic originating from one of those hosts.

Originating from **10.0.6.49** I found many alerts which were detected as scans, but none of them were targeted at any external addresses which would commonly be the case of a host infected with code red. Some traffic I did see which causes me to believe that this

host is possibly compromised with another trojan is displayed in the following chart. Some of the traffic has been removed due to the large volume.

Event Name	Detect Time	Target Address	Target Port	Source Address	Source Port
Scan	7 Jan 2002 22:43:50 PST	10.0.153.211	7001	10.0.6.49	7000

Scan	7 Jan 2002 21:01:13 PST 10.0.153.143	7001 10.0.6.49	7000

The reason I believe this traffic may represent a problem is that port 7000 is commonly associated with a Trojan called Freak-88. Freak 88 is a client server program that allows attackers to launch denial of service attacks on victims using ping floods. If a host is infected with freak 88 the host will be used as a zombie to launch larger DDoS attacks. This Trojan affects Windows 2000 and Windows NT4 systems. More information on freak88 is available at the following link. http://www.tlsecurity.net/backdoor/freak88.htm To discover if this system is infected with freak88 open the task manager and look for a process called PROJECT1 and do an end process. The Trojan does not write to the registry and will not restart after being stopped. There is another explanation for this traffic that could be the use of the Andrew file system. The Andrew file system was discussed earlier.

SMB Name Wildcard

Event Name	count of Event Name	Distinct SRC	Distinct TGT
SMB Name Wildcard	908	32	25

- **Brief Alert Description**

SMB Name wild card I most likely triggering off the following string located in the payload of a packet.

```
00 D8 00 00 00 01 00 00 00 00 00 00 20 43 4B 41 ............ CKA
41 41 41 41 41 41 41 41 41 41 41 41 41 41 41 41 AAAAAAAAAAAAAAAA
41 41 41 41 41 41 41 41 41 41 41 41 41 00 00 21 AAAAAAAAAAAAA..!
00 01 ..
```

The source host in this case is requesting the NetBIOS information from the target host as part of the Windows file sharing protocol to obtain domain, user and host id Information. NetBIOS information is a great place for an attacker to do reconnaissance because of the information that NetBIOS queries will typically give you.

- **Defensive Recommendations**

  Unless totally necessary it is a good idea to disable Windows file and print sharing especially on critical servers. There are many CVE and CERT advisories for NetBIOS. A few are listed below:

  http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0288
  http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0347
  http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0673
  http://www.kb.cert.org/vuls/id/32650
  http://www.cert.org/incident_notes/IN-2000-02.html

If you do need these services than you may want to look into host based firewalls that will only allow connections from trusted sources. In this case I found no external addresses as a source or target for any of these alerts, but I would have in place a perimeter firewall blocking ports 137-139 TCP and UDP inbound and outbound. Typically you don't want external sources accessing internal file servers. This would prevent that.

- **Correlations**

Since all the target and source addresses were internal there will be no external correlations.

Watchlist 000220 IL-ISDNNET-990517

Event Name	count of Event Name	Distinct SRC	Distinct TGT
Watchlist 000220 IL-ISDNNET-990517	307	4	6

- **Brief Alert Description**

A watch list is typically a custom snort rule that watches for connection attempts from or to a pre defined set of addresses. You would typically set up a watch list to alert you if there are connection attempts from a subnet that you have already discovered to be hostile. In this case I believe that the watch list is looking for connections from the 212.179.*.* network block. Whois information for that block returned the following:

```
European Regional Internet Registry/RIPE NCC (NET-RIPE-NCC-)
   These addresses have been further assigned to European users.
   Contact info can be found in the RIPE database, via the
   WHOIS and TELNET servers at whois.ripe.net, and at
   http://www.ripe.net/perl/whois/
   NL

   Netname: RIPE-NCC-212
   Netblock: 212.0.0.0 - 212.255.255.255
   Maintainer: RIPE

   Coordinator:
      Reseaux IP European Network Co-ordination Centre Singel 258
(RIPE-NCC-ARIN)  nicdb@RIPE.NET
      +31 20 535 4444

   Domain System inverse mapping provided by:

   NS.RIPE.NET                 193.0.0.193
   NS.EU.NET                   192.16.202.11
   AUTH03.NS.UU.NET            198.6.1.83
   NS2.NIC.FR                  192.93.0.4
   SUNIC.SUNET.SE              192.36.125.2
   MUNNARI.OZ.AU        128.250.1.21
   NS.APNIC.NET                203.37.255.97

   To search on arbitrary strings, see the Database page on
   the RIPE NCC website at http://www.ripe.net/perl/whois/
```

The following IP addresses were the sources for all of the watch list alerts.

Source Address	count of Source Address
212.179.35.118	231
212.179.35.119	64
212.179.38.137	9
212.179.28.133	3

These source IP addresses attempted to access the following internal GIAC hosts.

Target Address	count of Target Address
10.0.153.148	156
10.0.153.162	72
10.0.153.143	36
10.0.153.178	31
10.0.150.220	9
10.0.5.97	3

- **Defensive Recommendations**

Since this network seems to be considered hostile I would consider just blocking it from accessing internal hosts all together. As far as I am concerned if there are legitimate reasons for hosts on that network to access yours then they will complain to their ISP which will turn around and ask GIAC University why they are being blacklisted. At this point you can explain to them that you have had suspicious traffic originating from their address space and if they can fix the problems on their end then you will lift the access control list.

- **Correlations**

I found no correlations on SANS, Incidents.org, or Google for these external source addresses. I did however look into other internal events with a target address in the 212.179 address space and I found the following

Detect Time	Event Name	Source Address	Target Address	Target Port	Source Port
7 Jan 2002 09:31:07 PST	Scan	10.0.88.183	212.179.218.94	1214	1770
7 Jan 2002 09:31:04 PST	Scan	10.0.88.183	212.179.218.94	1214	1770
7 Jan 2002 09:20:53 PST	Scan	10.0.88.183	212.179.218.94	1214	1740
5 Jan 2002 14:00:23 PST	Scan	10.0.150.209	212.179.236.241	6257	6257
4 Jan 2002 17:22:29 PST	Scan	10.0.150.209	212.179.249.81	6257	6257
4 Jan 2002 17:17:09 PST	Scan	10.0.150.209	212.179.199.196	6257	6257
4 Jan 2002 17:15:32 PST	Scan	10.0.150.209	212.179.199.196	6257	6257
4 Jan 2002 16:55:29 PST	Scan	10.0.150.209	212.179.238.135	6257	6257
4 Jan 2002 16:50:45 PST	Scan	10.0.150.209	212.179.238.193	6257	6257
4 Jan 2002 16:49:27 PST	Scan	10.0.150.209	212.179.201.27	6257	6257
4 Jan 2002 16:48:44 PST	Scan	10.0.150.209	212.179.238.193	6257	6257

I would assume the 1214 traffic to be associated with Kazza www.kazza.com. Kazza is a file-sharing engine much like Napster that also is a very good source for downloading viruses and Trojans. I couldn't find an explanation for port 6257 traffic so I would recommend that further investigation be done as to the reason for this traffic.

FTP DoS ftpd globbing

Event Name	count of Event Name	Distinct SRC	Distinct TGT
FTP DoS ftpd globbing	189	3	2

➢ **Brief Alert Description**

This attack is targeting servers running a version of FTP developed by Washington University called Wu-Ftpd. Wu-Ftpd allows clients to have files available for ftp actions based on "file globbing" patterns. The implementation of file globbing that is used by Wu-Ftpd contains a heap corruption vulnerability that allows an attacker to execute arbitrary code on a remote server

Target Address	count of Target Address
10.0.153.164	163
10.0.150.145	26

Source Address	count of Source Address
12.3.135.250	130
12.3.134.202	33
198.173.24.162	26

Whois returned the following information for these source addresses

Whois look up on: **12.3.134.202 and 12.3.135.250** using server:whois.arin.net at port:43

Results:

```

```

Database last updated on 10-Feb-2002 19:55:25 EDT.

It appears that the 12.3 address space belongs to Lycoming College. I would assume that there is a legitimate reason that they are attempting to access FTP services on the GIAC network. If there were a legitimate reason for this access I would consider these to be false alerts. However I would be more concerned about the alerts originating from 198.173.24.162. This address belongs to Verio Inc., who provides DSL and dialup Internet access. I would want an explanation as to why this address is attempting to use FTP services on your network.

➢ **Defensive Recommendations**

First off I would recommend using a service besides FTP to transfer files. You may want to look into secure FTP or SCP if external file sharing is necessary. If there is not a legitimate reason for these hosts to be accessing FTP servers on your network then you may want to block port 20 and 21 on your perimeter firewall. If you are running Wu-Ftpd I would also suggest patching your systems with the patches available from the following website. There is also a good explanation on the exploit associated with Wu-Ftpd.
http://www.securiteam.com/unixfocus/6U00V0035Q.html

➢ **Correlations**

I found no correlations for these source IP addresses on Incidents.org, the SANS web site or Google.

WEB-MISC Attempt to execute cmd

Event Name	count of Event Name	Distinct SRC	Distinct TGT
WEB-MISC Attempt to execute cmd	153	12	5

➢ **Brief Alert Description**

These alerts were most likely caused by the DoS.Storm.Worm. What this worm does is looks for Microsoft IIS servers and when it finds one it infects it with the worm. The worm attempts to find vulnerable systems on the internet. It exploits a Web Server Folder Traversal vulnerability that is described at the following web site.
http://www.microsoft.com/technet/security/bulletin/MS00-078.asp
The Following technical description of the worm is from the Symantec Security response website at http://securityresponse.symantec.com/avcenter/venc/data/dos.storm.worm.html
"When the worm finds a vulnerable system, it copies itself to the targeted system and sets it up to automatically run the worm, effectively making that system a zombie that participates in the hacker's e-war. To make sure that the worm is run on next system startup, the worm adds the value 666 c:\winnt\system32\storm\start.bat to the registry keys HKEY_LOCAL_MACHINE\Software\Microsoft\,
Windows\CurrentVersion\RunServices, and
HKEY_LOCAL_MACHINE\Software\Microsoft\
Windows\CurrentVersion\Run
This worm has two payloads:

A denial of service attack is initiated against http:/ /www.microsoft.com.
An email bombing session is started that sends email messages containing an obscene message to gates@microsoft.com."

The following tables represents the sources and targets of this alert.

Source Address	count of Source Address	Target Address	count of Target Address
203.229.99.13	22	10.0.150.83	52
194.226.220.22	16	10.0.5.95	36
130.212.18.250	14	10.0.5.96	33
130.82.102.68	14	10.0.5.92	21
203.229.98.65	14	10.0.5.245	11
203.229.98.10	11		
211.93.8.74	11		
211.181.253.31	11		
203.229.99.115	11		
130.251.80.10	10		
203.229.99.74	10		
203.229.99.1	9		

I decided to look into the source addresses to see if they were possibly hostile hosts. The following whois information is regarding the sources of this alert.

203.299.9*.*

➢ **Defensive Recommendations**

First of all I would contact the Administrator at Asia Pacific and inform them that hosts in their address space have been attacking your network and that you are going to block their entire address space from accessing your network. Alerting them to this fact will probably not accomplish much so I would put an ACL in place on your perimeter firewall blocking the address block or at least the hosts. Secondly I would contact the administrators at the University networks and inform them that they may have compromised hosts on their network. It would be a safe assume that they don't have very strict security measures in place therefore compromised hosts are likely. I would assume that these are all critical servers as they have been previously identified as University Web Severs. If these servers are running IIS I would get a virus detection tool like Symantec antivirus and run it on the hosts targeted by this alert. Symantec also has removal instructions at the following link.
http://www.symantec.com/avcenter/venc/data/dos.storm.worm.html
I would pay special attention to 10.0.5.92 as I believe it may be compromised. You may consider rebuilding that server and installing all the latest security patches available from Microsoft.
http://www.microsoft.com/technet/treeview/default.asp?url=/technet/security/bulletin/MS00-078.asp

➢ **Correlations**

The following site reported 1 attack(s) from - 203.229.98.10
http://www.jaosa.net/codered.txt
Most of the other source IP addresses have been reported to incidents.org numerous times. This would indicate that it is definitely a good idea to consider blocking these addresses from accessing your network.

WEB-CGI scriptalias access

Event Name	count of Event Name	Distinct SRC	Distinct TGT
WEB-CGI scriptalias access	96	1	1

➢ **Brief Alert Description**

According to CVE there is a vulnerability in apache that the "ScriptAlias directory in NCSA and Apache httpd allowed attackers to read CGI programs."
http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0236
All of these alerts were generated from one source and target at one of the University's Web Servers. The whois information returned the following on the possible hostile IP address.
Whois look up on: 24.180.201.71 using server:whois.arin.net at port:43

Results:
@Home Network (NETBLK-HOME-2BLK)HOME-2BLK 24.176.0.0 - 24.183.255.255
@Home Network (NETBLK-BLTMMD1-MD-3) BLTMMD1-MD-3 24.180.192.0 - 24.180.207.255

➢ **Defensive Recommendations**

I would suggest blocking this IP address from accessing your network and you may want to advise their ISP of this traffic.

➢ **Correlations**

The following traffic was reported on the sans website from a previous date range of MY.NET traffic.
http://www.sans.org/capsans/snort/SnortA54.txt

```

```

spp_http_decode: CGI Null Byte attack detected

Event Name	count of Event Name	Distinct SRC	Distinct TGT
spp_http_decode: CGI Null Byte attack detected	96	1	1

➢ **Brief alert Description**

This alert is detecting a 'null byte' in the CGI string. A null byte would be %00, what that does is mask system commands from CGI security checks by hiding the commands behind a null byte. A packet of data that CGI scripts do not detect unless specifically

programmed to look for them. Basically a NULL Byte attack is when an attacker appends a %00 to a URL, in order to confuse a Perl script about where the end of it's input is. These alerts all originated from one IP address 24.180.201.71 and were all targeted at one of the University's web servers 10.0.5.96. One thing to note is that the source for these alerts is the same as the source of the previous WEB-CGI scriptalias access alerts. It appears to me that the person who this address belongs is trying to break into this web server using various CGI exploits, although I don't believe them to have been successful.

- **Defensive Recommendations**

Since the IP address generating these alerts has been very actively targeting this GIAC webserver I would again recommend that it be blocked from accessing GIAC University.

- **Correlations**

See the correlations section for the previous alert.

EXPLOIT x86 NOOP

Event Name	count of Event Name	Distinct SRC	Distinct TGT
EXPLOIT x86 NOOP	82	3	3

- **Brief Alert Description**

The NOOP alert is triggered when snort detects a number of contiguous bytes that could be no-operation machine language codes. NOOPs are often used to pad out buffer overflow attacks, so this alert is indicating that it may have found an attempt to run attack code via a buffer overflow exploit.

Target Address	count of Target Address	Source Address	count of Source Address
10.0.150.190	80	24.95.245.166	80
10.0.153.185	1	207.46.177.148	1
10.0.153.211	1	211.233.30.231	1

All of the traffic originating from 24.95.245.166 was targeted at port 20 which is the data exchange port for the FTP protocol. These could either be false alerts because of data that's being transferred, or this host could be trying to execute a buffer overflow on the 10.0.150.90 host. I also noticed Anonymous FTP access attempts from this host targeted at the same host. Since this is an external host trying to access FTP services on GIAC University's network I did a whois on the source address. I found the following.

Whois look up on: 24.95.245.166 using server:whois.arin.net at port:43

Results:
ServiceCo LLC - Road Runner (NET-ROAD-RUNNER-3-A)
13241 Woodland Park Road
Herndon, VA 20171
US

Netname: ROAD-RUNNER-3-A

Netblock: 24.92.160.0 - 24.95.255.255
Maintainer: SCRR

Coordinator:
ServiceCo LLC (ZS30-ARIN) abuse@rr.com
1-703-345-3416

Domain System inverse mapping provided by:

DNS1.RR.COM	24.30.200.3
DNS2.RR.COM	24.30.201.3
DNS3.RR.COM	24.30.199.7
DNS4.RR.COM	65.24.0.172

Record last updated on 30-Aug-2001.
Database last updated on 11-Feb-2002 19:56:34 EDT.

Road Runner is an ISP in Texas and parts of the east coast. I would consider this traffic to be possibly hostile and I believe that further investigation is necessary to determine if 10.0.150.190 is compromised since this host is believed to be a university FTP server. Looking at the events originating from 10.0.150.190 I found nothing that appeared to be hostile or indicate that the system is compromised.

- **Defensive Recommendations**

Since buffer overflows exploit vulnerable services I would try to ensure that all the servers targeted bye these alerts are up to the latest patch level and I would also consider blocking FTP access into the network from external sources. I would also recommend further investigation of the host 24.95.245.166 to see if there is a legitimate reason for them to be accessing the internal GIAC FTP servers.

- **Correlations**

I found no correlations for these external source addresses on the SANS site, Google or Incidents.org.

OOS Event

Event Name	count of Event Name	Distinct SRC	Distinct TGT
OOS Event	64	14	6

- **Brief Alert Description**

OOS events are reported when snort sees packets that are out of specification as described in the RFC's. This could include but is not limited to bad TCP flag combinations, invalid sequence numbers, and illegal fragments. OOS packets are often indications of packet crafting. Which can be used for various reconnaissance purposes. For example if an attacker crafts a packet with illegal flag combinations and sees how a host responds he has some indication as to the OS the host is running. By determining the

operating system of the remote host they know have a better idea how to plan their attack. This is known as OS Finger Printing.

Top 5 Source Address	Count of Source Address	Top5 Target Address	Count of Target Address
144.122.42.38	16	10.0.88.162	36
195.132.240.41	10	10.0.150.204	13
24.158.117.251	9	10.0.150.143	8
130.104.19.73	8	10.0.153.206	5
4.61.46.216	6	10.0.150.220	1

I looked at other traffic originating from these source addresses and found that **144.122.42.38** generated the following alerts. Null scan!, OOS Event, SCAN FIN, SCAN XMAS, SYN-FIN scan!, and Scan. This IP address has the following information registered with arin.net.

Middle East Technical University (NET-METU-NET)
METU Computer Center Inonu Bulvari - ODTU

NS1-AUTH.SPRINTLINK.NET	206.228.179.10
AUTH60.NS.UU.NET	198.6.1.181

Record last updated on 27-Oct-1998.
Database last updated on 11-Feb-2002 19:56:34 EDT.

All of these source IP addresses were the sources of numerous scans and other events. I would consider them to be hostile.
As for the targets of these alerts I decided to look into traffic originating from them in order to determine if they have been possibly compromised. What I did was look at all traffic originating from these target IP addresses with a destination being one of these source addresses. I figure that if there was a hostile code in one of these OOS packets than there will be connections from the compromised host back out to the attacking host or another host that the attacker has under their control.

10.0.88.162

This appears to be traffic associated with Kazza. Kazza is an Internet file sharing service that was discussed earlier. I would assume that this host is not compromised.
From the other addresses I saw traffic that appeared to be Napster and more Kazza traffic. I would assume that these are not a high priority.

- **Defensive recommendations**

Again depending on the security policy for GIAC University you may want to consider disallowing Napster and Kazza traffic.

- **Correlations**

I found no correlations for these external addresses on Google, The SANS site, or Incidents.org

Possible trojan server activity

10.0.150.220	2	213.77.129.108	2		
10.0.5.44	1	10.0.5.83	1		

- **Brief Alert Description**

These alerts are triggering off the target or the source port of 27374, which is commonly associated with the sub-seven Trojan. Sub seven is similar to Back Orifice or NetBus. The effect of this Trojan will enable people to access your system over the Internet with out you knowing. The Sub Seven Trojan can also be configured to inform someone when its infected computer connects to the Internet, and tells that person all the information

about you they need to use the Trojan against you. The notification will take place via ICQ or email. Numerous ICQ connections originating from any of the systems targeted by this alert would be a good indication that the system is compromised. There are very detailed description of Sub Seven located at the following links…
http://www.sans.org/newlook/resources/IDFAQ/subseven.htm
http://www.symantec.com/avcenter/venc/data/backdoor.subseven.html

Possible trojan server activity	5 Jan 2002 00:06:21 PST	10.0.5.83	7938	10.0.5.44	27374

Some of this traffic appears to be Kazza traffic targeted at port 27374 as a random ephemeral port but I am more concerned with the traffic that is not associated with Kazza.
When I remove the Kazza traffic from the previous list I get a smaller number of hosts that may be infected.

Table 2

There are two other explanations for this traffic. Port 7938 is associated with Legato Network Backup Software that could be running on some of the hosts in question. It would seem that 10.0.5.83 would then be a back up server. The other port in question is 8733, which is commonly associated with the Ibus protocol. Ibus is a java messaging protocol, and further research as to why it is being used on university computers would

be necessary. Another note is that all the traffic that is not related to Kazza is from internal sources to internal targets.

- **Defensive Recommendations**

I would thoroughly check all the targets and internal sources of this alert for possible compromise and there are detailed instructions on doing so at following Symantec link. http://www.symantec.com/avcenter/venc/data/backdoor.subseven.html
I would also consider blocking port 27374 at the perimeter firewall inbound and out. I would also check the servers listed in the **table 2** for ICQ or email traffic to external sources as this could indicate that they have been compromised and communicating with attackers on the Internet.

- **Correlations**

I found no correlations for these external addresses on Incidents.org, The SANS site or Google.

TCP SRC and DST outside network

Event Name	count of Event Name	Distinct SRC	Distinct TGT
TCP SRC and DST outside network	37	9	5

- **Brief Alert Description**

This alert is triggering off snort seeing packets on the internal network that are not destined to or originating from an internal host. This is most likely signs of packet crafting originating from an internal host that has been compromised. It is extremely difficult to track down the true source of spoofed packets unless you can get the mac address or the physical address of the NIC card that's sending them. That is assuming that they are not passing through a router. If they are passing through a router then the Mac address you will see is that of the last hop router. I believe this could also be an indication of source routing. An attacker could specify in his source route that the packets are to pass through your router.

All of the traffic generating these alerts was from the 169.254.0.0 address space and was destined for the same. I noticed that all the traffic appeared to be NetBios connections either originating from or targeted for port 139. I also found an interesting quote that someone posted to SANS that said 169.254 addresses could also be explained as "supposed to be for newer DHCP clients that cannot get an internal address" Curtis L. Blais.

The who is information for the 169.254 address block returned the following information.

> Whois look up on: 169.254.146.18 using server:whois.arin.net at port:43
> IANA (NETBLK-LINKLOCAL)
> Internet Assigned Numbers Authority
> 4676 Admiralty Way, Suite 330
> Marina del Rey, CA 90292-6695

US
Netname: LINKLOCAL
Netblock: 169.254.0.0 - 169.254.255.255
Coordinator:
Internet Corporation for Assigned Names and Numbers (IANA-ARIN) res-ip@iana.org

BLACKHOLE-2.IANA.ORG 192.0.32.19

➢ **Defensive Recommendations**

If this traffic is originating from within your network it is highly likely that you have an internal host that is compromised. I would recommend running tcpdump with the –e option which will allow you to view the mac address information. Once you do this you can write filters that will allow you to narrow down the traffic. I would recommend filtering on the 169.254 addresses and try to find the mac address where these packets are originating. Once you know the Mac address, write a filter based on that address and try to locate some "normal" or un-spoofed traffic to find out the real IP address of the compromised system. Another recommendation would be to implement egress filtering at your perimeter router. What egress filtering does is block any traffic outbound that is not originating from your address space. I would use the following paper written by Chris Brenton called "What is Egress Filtering and How Can I Implement It?" This paper gives an excellent of the problem and also real world examples of a solution. It is available at the following link. http://rr.sans.org/firewall/egress.php I also have to wonder if these addresses are some type of reserved addresses that shouldn't be routed in the first place. Then I may want to look at the traffic originating from the DHCP server which as earlier stated could assign these addresses. That would not however explain why other people have seen scans for NetBios ports originating from these IP addresses. If this just a problem with a dhcp server, I would still recommend egress filtering to avoid spoofed traffic from leaving your network in the future. I believe that this traffic requires further investigation before a concrete conclusion can be drawn as to the reason behind it.

➢ **Correlations**

There was a report of NetBios scans originating from the 169.254. address range at the following link.
http://www.theorygroup.com/Archive/Argus/1999/msg00165.html

Curtis Blais reported to incidents.org seeing NetBios scans of his network originating from the 169.254 address space. An example of the traffic is following.

```
11:15:44.684687 169.254.65.17.1078 hawk.MY.NETWORK.netbios-ssn:
  S 6292402:6292402(0) win 8192 (DF)

http://www.incidents.org/archives/intrusions/msg00055.html

INFO FTP anonymous FTP

Event Name	count of Event Name	Distinct SRC	Distinct TGT
INFO FTP anonymous FTP	21	6	2

➢ **Brief Alert Description**

FTP anonymous access is referring to someone trying to access an FTP server using the default anonymous login. FTP is the File Transfer Protocol. It is used primarily for transferring files from one host to another or from site to site. These alerts were targeted at 10.0.150.190 which has been identified as one of the University's FTP servers. All the sources for this alert were external and it should be looked into as to why they are attempting to logon to the FTP server anonymously. I would think that if they had a legitimate reason to access this server they would have a user name and a password. The following addresses were sources for this alert.

Source Address	count of Source Address
24.95.245.166	14
62.163.158.112	2
66.30.59.155	2
193.253.42.45	1
208.242.127.31	1
24.13.140.41	1

It appears that 24.95.245.166 tried 14 times to access this server anonymously 10 times on the 6th of January 2002 and 4 more times on the 7th. I find this to be curious so I did a who is on the address and found that the address belongs to Road Runner which is an ISP. This is most likely a home user. They may be a student that is allowed to access this ftp server maybe to get assignments or something but again I would think that they would have a user name and a password.

➢ **Defensive Recommendations**

I will make several recommendations in this case the first of which is don't use FTP if at all possible. There are many exploits that target FTP servers that allow the attacker to gain root access to the host. Another problem with FTP is that the username and password are transferred across the wire in the clear, meaning that anyone with a sniffer now knows your username and password. Rather than FTP I would consider using an service such as secure ftp or scp which will do encrypted authentication. If FTP is a necessity then I would recommend disabling anonymous access to all FTP servers.

➢ **Correlations**

I found no correlations for these source addresses on Google, Incidents.org or the SANS site.

Incomplete Packet Fragments Discarded

Event Name	count of Event Name	Distinct SRC	Distinct TGT
Incomplete Packet Fragments Discarded	17	3	3

- **Brief Alert Description**

Packet Fragments are often used to conceal malicious code and to avoid Intrusion detection systems. Attackers also use fragments to pass through not statefull firewalls. In this case the alert is being generated by snorts defrag plugin which is used to reassemble fragments to look at the contents. What this alert means is that while reassembling the packet snort never saw the final fragments and discarded them. You typically don't want to see fragmentation on your network and this alert indicates that you have anomalous fragments because snort never received the last fragment.
These alerts were targeted at 10.0.88.165, 10.0.150.143, and 10.0.153.207. I believe that these are not necessarily malicious because the originate from 3 separate hosts and each source targets the same target for each alert. I would want to understand further why we would be seeing fragmentation. One thing I noticed that was rather strange was that one of the source addresses was 172.16.2.100. 172 is a reserved address space like 10.0 and should not be routed on the internet. I would consider this to be a possibly spoofed source address or at least very strange and it would require further investigation as to how this could be possible with out spoofing. I looked into other traffic originating from the target of the alert with this strange source address and I didn't see anything out of the ordinary.

- **Defensive Recommendations**

I would suggest deploying a statefull firewall at the perimeter of the network so that attackers cannot bypass acl's on non statefull routers. I would also check the targeted hosts for signs of compromise. You may also consider looking into the source addresses of these alerts to see if they have a legitimate reason to be accessing the GIAC university network. They are listed bellow.
172.16.2.100
202.102.29.141
210.76.63.49

- **Correlations**

I obviously found no correlations for the 172.16.2.100 address. I did find correlations for the other two but they were in foreign languages that I do not speak. There was nothing on incidents.org or the SANS site.

High port 65535 tcp - possible Red Worm - traffic

Event Name	count of Event Name	Distinct SRC	Distinct TGT
High port 65535 tcp - possible Red Worm - traffic	13	4	4

➢ **Brief Alert Description**

I discussed what The code Red worm Is in detail in a previous section labeled High port 65535 UDP - possible Red Worm – traffic. This is the TCP version of the alert since Red Worm uses both TCP and UDP. I am very concerned with the highlighted sections of the following chart these are the 13 instances of this alert for the time period I analyzed. The non highlighted traffic I assume to be related to Kazza, but it may be a good idea to investigate that host further. The other two hosts are most likely compromised by the Code Red worm and I would recommend applying the defensive recommendations I made earlier to these hosts. I will copy those recommendations into this alert analysis so you don't have to go back and read them.

Detect Time	Target Address	Target Port	Source Address	Source Port
7 Jan 2002 19:46:47 PST	10.0.152.249	1460	10.0.60.8	65535
7 Jan 2002 19:46:47 PST	10.0.152.249	1460	10.0.60.8	65535
7 Jan 2002 19:46:50 PST	10.0.152.249	1460	10.0.60.8	65535
5 Jan 2002 13:56:33 PST	10.0.88.162	1214	195.219.155.203	65535
5 Jan 2002 13:56:34 PST	10.0.88.162	1214	195.219.155.203	65535
5 Jan 2002 13:56:32 PST	10.0.88.162	1214	195.219.155.203	65535
7 Jan 2002 19:46:47 PST	10.0.60.8	65535	10.0.152.249	1460
7 Jan 2002 19:46:47 PST	10.0.60.8	65535	10.0.152.249	1460
7 Jan 2002 19:46:47 PST	10.0.60.8	65535	10.0.152.249	1460
7 Jan 2002 19:46:47 PST	10.0.60.8	65535	10.0.152.249	1460

➢ **Defensive Recommendations**

There is a utility that is available from Dartmouth University written by William Stearns which will detect the adore files on an infected system. This utility is available at http://www.ists.dartmouth.edu/IRIA/knowledge_base/tools/adorefind.htm I would highly recommend that this tool be downloaded and run on all the hosts listed in the above tables. Another good recommendation would be to block emails to or from the following addresses adore9000@21cn.com, adore9000@sina.com, adore9001@21cn.com, adore9001@sina.com. The worm sends these email addresses your critical system information.

➢ **Correlations**

Since I am only concerned with these two internal hosts and not the traffic I assume to be Kazza there are no external correlations.

TOP TALKERS

This section focus on the top external, and overall source addresses from the Scans, Alert, and OOS data files. As well as the top GIAC University targets. For the external sources I have included Whois information, which helps in determining the legitimacy of the traffic as well as deciding if the source should be considered hostile.

Top Ten Source Addresses From Alert Files

Top Ten Alert Source Addresses

Source Address	Count of Source Address
10.0.5.202	30109
10.0.153.114	5544
10.0.153.146	4580
10.0.88.181	2930
10.0.70.177	2903
10.0.150.198	2173
10.0.150.41	1933
203.248.242.22	1898
10.0.151.79	1866
10.0.153.119	1864

Since most of these are internal addresses I would investigate each as to the traffic that is triggering these alerts. If the traffic is not malicious I would consider modifying your Snort rule set.

203.248.242.22 This address belongs to the Asian Pacific Network and should be considered Hostile. I would suggest blocking access to GIAC University from this address.

This report shows the top ten internal hosts that were scanned by external addresses. These hosts should be checked for signs of compromise.

OOS Top Talkers

For my selected date range I had a surprisingly low number of OOS events. The total count was 64. I believe that most of the packets were considered to be OOS because of invalid TCP Flag combinations. The reason for these OOS packets could be OS fingerprinting and certain types of scans like Syn-Fin scans. I will show examples of Syn-Fin scans after the top OOS talkers reports.

```

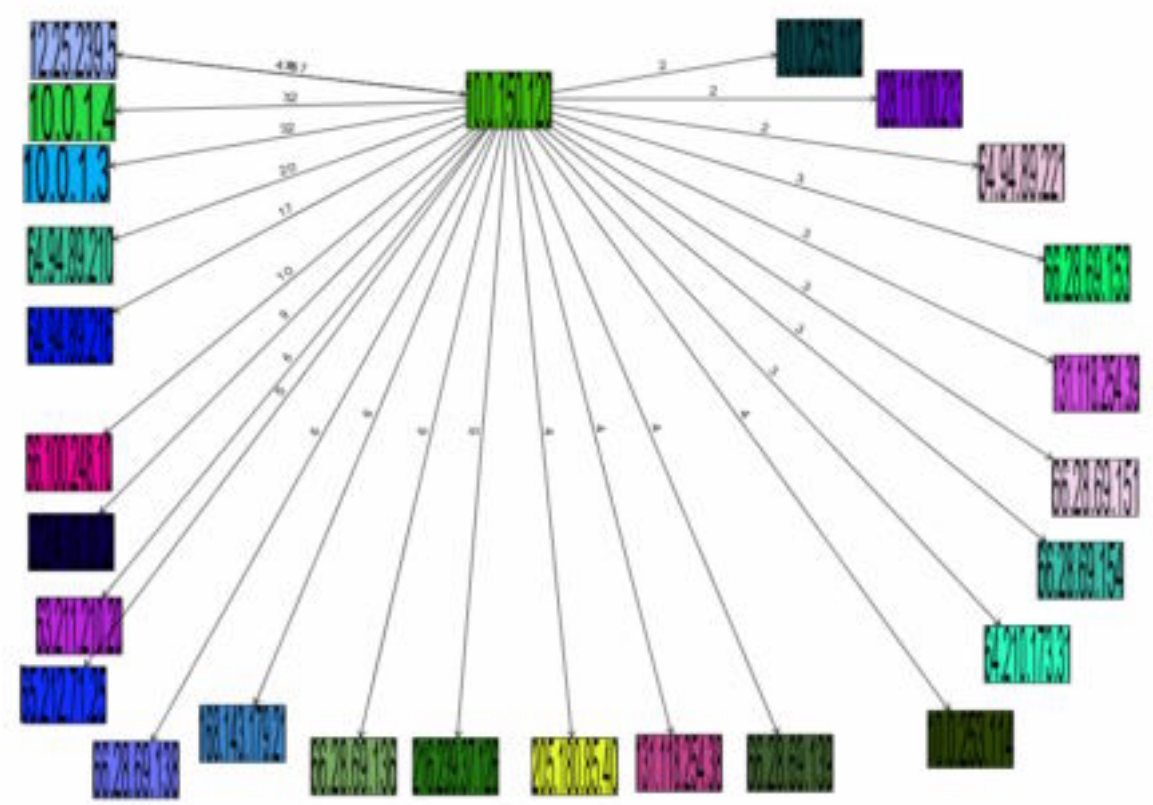
The following OOS alerts seem to be Syn-Fin scans. Note the flags:

Event Name	Detect Time	Target Address	Target Port	Source Address	Source Port	TCP Flags
OOS Event	7 Jan 2002 16:15:01 PST	10.0.88.162	1214	144.122.42.38	2718	**..SF....**
OOS Event	8 Jan 2002 16:08:46 PST	10.0.153.206	6699	192.116.55.2	1089	**..SF....**
OOS Event	8 Jan 2002 08:35:27 PST	10.0.150.204	1697	24.158.117.251	217	**..SF....**

The first one could be some one scanning for a Kazza Server that's listening. They may know of an exploit that targets hosts running Kazza.

LINK GRAPH

I decided to do my link graph on all the traffic to and from 10.0.150.120, which is a host that I have determined to be compromised. The link graph shows all the traffic that this host has had with other hosts and the direction of the traffic. From looking at graphical representations of data it gives an analyst a way to find a starting point as to where anomalous or malicious is occurring most. By looking at the graphical representation you will notice an anomalous amount of traffic between 12.25.239.5 and the compromised host. The numbers on the arrows represent the number of events in the Scan, Alert, and OOS data
files.



Brief Analysis Process

Included in the data files I chose there were over a million records. These records were scans, OOS, and snort alerts. Each type of log file was formatted differently so with out normalizing them I wouldn't have a chance at descent analysis. First I parsed out all the fields that I deemed to be important and exported them into CSV format. I did this using bits and pieces of various scripts that I found.
Once I had all the fields parsed out and converted to a CSV I then wrote a small program that would load them into a database. The first thing I had to do was to come up with a schema that would accommodate all the fields I was interested in. I used the following schema.

Event ID	Event Name	Protocol	Detect Time	Target Address	Target Port	Source Address	Source Port	Product	TCP Flags

I used the event ID field so that each event would have a distinct field that would not match any other record in the database. The event name was populated with the name of the Alert. The rest of the fields are self explanatory except for product. I used the product field to indicate the source of the alert. This field was populated with either OOS, Scan, or Snort, depending which file it came from. I also converted all the IP addresses to 10.0.*.* because I found they were much easier to work with.
Once I had all the data in a common database, I was able to issue queries and run reports across all the records I was supplied. The first thing I did was try to generate a simple topology of the network. I did this by looking for large amounts of traffic targeted to well known service ports such as port 25 for mail. I used Visio to generate the network map. I found that having an assumed topology as a reference gave me a good starting point and also helped me in determining the lethality of the alerts I was seeing. From that point on the process was mainly queries to generate the figures for my reports Queries were also issued to generate statistics as to number of events from particular sources, or count events of a particular event type targeted at a particular host.
I would like to note that the network topology was assumed based on the traffic patterns I saw in the supplied data files and that the only devices I added were a router, which I assume to be the gateway to the Internet, and the host running snort these two devices were not based on events I saw, rather it was assumed that they must be present.
