GIAC Reverse Engineering Malware (GREM)

Practical Assignment

Version 1.1 (added July 23, 2004)

Julia Hopkins

14/12/2004

Reverse Engineering “msrll.exe”

This paper is a description of the steps I took to reverse engineer a file called msrll.exe. It begins with a description my laboratory setup. Then I give an account of my behavioural and code analysis. Finally I discuss the implications of the functionality of the malware and suggest ways of avoiding infection.

Laboratory Setup

My laboratory setup consists of my host operating system and two virtual machines. My physical host is a Sony Vaio Notebook, model SVGN-S1HP. It is never connected to a production network. My host operating system is Microsoft Windows XP version 5.1.2600.1240 (Service Pack 2). On the host operating system I have installed VMWare Workstation for Windows version 4.5.2 build 8848. I have used this software to create my two virtual machines. The details are as follows: -

Virtual Machine 1: Microsoft Windows XP version 5.1.2600.1240 (Service Pack 2) , 224MB RAM, max of 4GB HD (IDE), host-only NIC

Virtual Machine 2: Linux Red Hat 9 – the Virtual Machine provided on CDROM by Lenny Zeltser during the course. “This Linux VMware machine was installed using CDs that were created from Red Hat Linux 9 ISO images downloaded from the <http://www.redhat.com>. This is a “minimal” installation that includes additional packages useful for malware analysis.”¹ The virtual machine has 64 MB RAM, a max of 2GB HD, and a host-only NIC.

The diagram below shows the IP addresses of the host, the virtual network and the two virtual ‘guest’ machines.

Properties of the Malware Specimen

The malware specimen is provided as a .zip file (msrll.zip). When unzipped with Winzip it has the following properties:-

Name: msrll.exe

Type of file: msrll.exe is a Microsoft Windows executable file which has been packed with ASPack. I obtained this information by running Bintext on msrll.exe (see screen shots below) . Bintext is a tool which extracts embedded strings from executables.

The string “!This program cannot be run in DOS mode” is commonly found in the first sector of windows executables and the string “.aspack” indicates that msrll.exe is packed with ASPack. The Windows dll names and functions visible in the second screen shot confirm that msr ll.exe is a Windows executable.

Size: 41,984 KB

MD5 Hash: 84acfe96a98590813413122c12c11aaa

Operating system it runs on: Windows XP and other MS Operating systems

Strings embedded into it: Most of the strings found by Bintext are obfuscated because the malware is packed. However, the following screenshots show some strings that are not obfuscated:-

File pos	Mem pos	ID	Text
A 0000004D	0040004D	0	!This program cannot be run in DOS mode.
A 00000178	00400178	0	.text
A 000001A0	004001A0	0	.data
A 000001F0	004001F0	0	.idata
A 00000218	00400218	0	.aspack
A 00000240	00400240	0	.adata
A nnnnnnnn	nnnnnnnn	n	MS-DOS

Behavioural Analysis

I started my analysis of the malware specimen using behavioural analysis. When I could go no further down a particular path of observation using this kind of analysis I returned to the path later using code analysis. The following is a description of my behavioural analysis:-

The first stage of my behavioural analysis involved the use of five system monitoring tools to find out what would happen in the background if I ran the malicious executable on my Windows XP virtual machine. I also wanted to record any changes that the running malicious executable made to the system :-

1. **Regshot v1.61e5 Final** - for changes to the Registry and file system
2. **Filemon v 6.07** – for monitoring file access
3. **Regmon v 6.06** – for monitoring registry access
4. **TDIMon v 1.0** – for monitoring network activity
5. **Microsoft Windows Task Manager version 5.1** – to view running processes

I began by using MS Windows Task Manager to familiarise myself with the processes running on my Windows XP virtual machine.

Then I prepared Filemon, Regmon and TDIMon for action on the Windows virtual machine.

I took my first snapshot of the registry and the file system (C:\ and subdirectories) using Regshot.

Then I started the capture function on each of the three monitoring tools and quickly double clicked on the msrl.exe icon on my desktop to execute it.

I let it run for about forty seconds during which I noticed that a process called msrl.exe appeared in Task Manager.

After the forty seconds I terminated the msrl.exe process from Task Manager.

Then I paused the capture function on the three monitoring tools before taking my second snapshot with Regshot.

This is what I found:-

First of all, Task Manager showed that the malicious executable started a new process with the same name as itself , msrl.exe .

I pressed the “compare” button in Regshot to compare the two snapshots taken in the steps above. The output (see Appendix A) showed several very interesting changes:-

A new key was created:

HKLM/SYSTEM/ControlSet 001/Services/mfm/Security

All changes to the HKLM/SYSTEM/ControlSet001 key also appeared under the HKLM/SYSTEM/CurrentControlSet key. HKLM/SYSTEM/CurrentControlSet is a pointer to whichever control set was used to boot the computer which was ControlSet001 in this case.

In this key, a new service was added: -

```
HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\mfm\Security:  
01 00 14 80 90 00 00 00 9C 00 00 00 14 00 00 00 30 00 00 00 02 00 1C 00 01 00 00  
00 02 80 14 00 FF 01 0F 00 01 01 00 00 00 00 01 00 00 00  
HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\mfm\Type:  
0x00000120  
HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\mfm\Start:  
0x00000002  
HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\mfm\ErrorControl:  
0x00000002  
HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\mfm\ImagePath:  
"C:\WINDOWS\system32\mfm\msrll.exe"  
HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\mfm\DisplayName:  
"RII enhanced d rive"  
HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\mfm\ObjectName:  
"LocalSystem"
```

The display name of the service is "RII enhanced drive" but the underlying executable (ImagePath) is C:\WINDOWS\system32\mfm\msrll.exe – the malicious executable. The Start value is set to 2 which means that the service starts automatically when the operating system is started. The ObjectName value is set to LocalSystem which means that the service (msrll.exe) is run with system privileges.

Interestingly, a new value was added to the Registry which tells Windows XP's built in firewall to enable msrll.exe for any source. In other words, the malware is configuring the firewall to let it talk out:

```
HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\SharedAccess\Parameters\FirewallPolicy\StandardProfile\AuthorizedApplications\List\c:\WINDOWS\system32\mfm\msrll.exe: "C:\WINDOWS\system32\mfm\msrll.exe:*:Enabled:msrll"
```

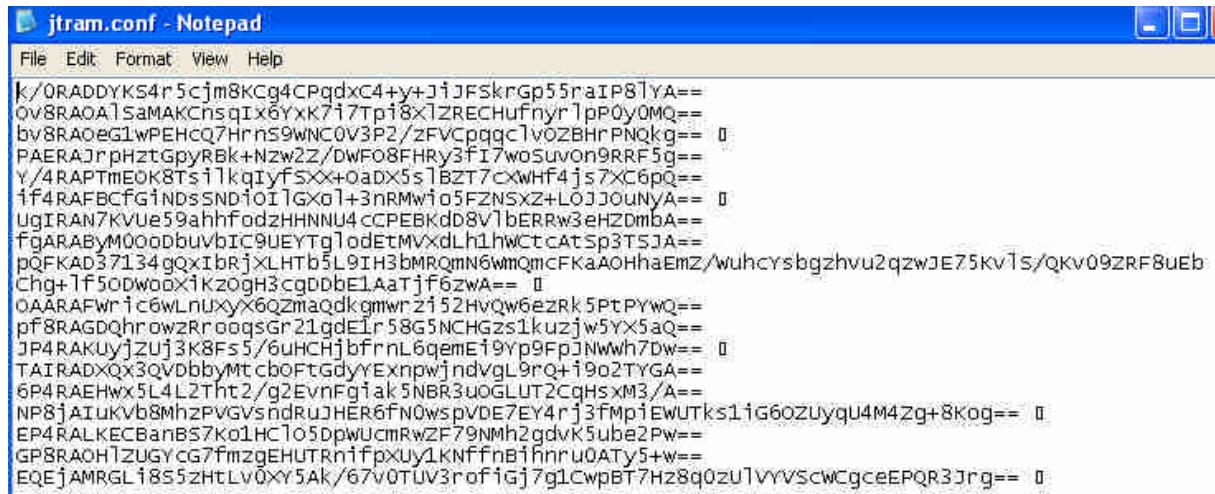

Regshot shows that a new folder called mfm was created in C:\WINDOWS\system32 and that two new files were dropped into the mfm folder. The files are called **jtram.conf** and **msrll.exe**. The malware also deleted itself from the desktop.

Incidentally, the following internet cache files were modified but I am uncertain whether this has any significance.

```
C:\Documents and Settings\julia\Cookies\index.dat  
C:\Documents and Settings\julia\Local Settings\History\History.IE5\index.dat  
C:\Documents and Settings\julia\Local Settings\Temporary Internet  
Files\Content.IE5\index.dat
```

Quick Summary of Regshot findings

The malware creates two new files in C:\windows\system32\mfm. One of the files is an exact copy of the original which I established by running MD5Sum on it to obtain its hash value. The other is called jtram.conf, perhaps a configuration file for msrl.exe. I opened it with notepad and below is a screenshot of what it contained: -

jtram.conf - Notepad

```

The contents of jtram.conf are a set of what look like 18 encrypted values, all ending in " = " which is the "assignment" function in C . Six of them are assigned to what I think is a NULL character, perhaps for initialisation. Fifteen of the values are 50 characters long. Two of the values are 74 characters long and one value is 126 characters long. I stopped and started msrl.exe several times and established that jtram.conf contains a completely different set of values every time. The MD5 hash of jtram.conf therefore changes each time the malware runs.

The malware also creates a new service configured to run every time the computer starts up. Its display name is "RII enhanced drive" but the underlying executable is the malware itself, msrl.exe. The service runs with system privileges. The malware also tells Windows XP Internet Connection Firewall to allow msrl.exe to "talk out". Finally, msrl.exe deletes itself from the place that it is executed from in the first place.

Regmon offered nothing new. It did however confirm that the malware creates a service called RII enhanced drive and that it is actually created by services.exe working on behalf of the malware.

Filemon showed the malware looking for various dll files in the location it was executed from (the desktop in this case). When it couldn't find them there it looked in C:\Windows\system32 for them. Filemon confirmed all the file-related activity found by Regshot. However, when these transactions were over, Filemon recorded further activity:-

The malware persistently looked for a file called rsaenh.dll , a cryptographic service provider, in the mfm folder. When it couldn't find it there it looked for it in C:\Windows\system32. It found it here and read from it. This indicates that the malware uses encryption.

Then it repeatedly attempted to open the path C:\dev\random. I knew that this directory didn't exist on my system and considered that perhaps this folder existed on the malware author's computer when he was creating the malware and he forgot to change the path before distributing his virus.

Each time the malware failed to open C:\dev\random, it opened jtram.conf and wrote something to it. Then it tried to access the folder again. Eventually it gave up and closed jtram.conf. This is obviously the point at which jtram.conf gets its contents but where are they coming from if the malware can't access C:/dev/random? Maybe they are coming from the file that the malware spent some time reading from just before this step - rsaenh.dll.

I tried creating the c:\dev\random directory on my Windows VM and running Filemon again to see what would happen. The malware behaved in exactly the same way as before even though it was able to open the C:\dev\random folder this time.

However, I ran an internet search on C:\dev\random and discovered the probable reason that the malware was trying to access this folder. It turns out that /dev/random is a feature of the Linux kernel and of certain *BSD kernels. It is a character device that provides you with "high quality, cryptographically strong , random data"¹. This behaviour ties in with the previous observation of the malware opening rsaenh.dll, a cryptographic service provider . Maybe rsaenh.ll's encryption process requires some random input, or what is called a "salt" in encryption terms . It is unusual that the author has included this capability in his code because behaviour so far indicates that the Trojan is targeted at MS Windows operating systems. However, MS Windows operating systems don't support the dev/random device. Maybe the malware was compiled on a Linux operating system. It is good news for me if the random aspect of the author's text obscuration plans doesn't work!

TDIMon revealed that msrll.exe is listening on TCP port s **2200** and **113** on all local ip addresses (0.0.0.0:2200 and 0.0.0.0:113). TCP Port 113 is used for Ident requests. When an IRC server receives a connection request it will typically send an Ident request to the connecting client on TCP port 113 to establish the connecting user's identity. This is the first indication that the malware may be trying to connect to an IRC server. In order to ensure a successful connection it needs to listen on port 113 to provide the necessary identification information to the irc server. TCP port 2200 is not commonly used for anything in particular. Maybe it is being held open as a back door to the infected computer .

TDIMon also showed svchost.exe making a DNS request from UDP port 10 42 (to 192.168.46.1:53).

The relevant lines from the TDIMon output log can be found in Appendix A.

Having seen that the malware is instigating some network traffic, I decided to capture some packets using a sniffer located on my Linux virtual machine. I started Snort v2.0.4 in promiscuous mode from the Linux virtual machine and double-clicked on

¹ EGD: The Entropy Gathering Daemon by Brian Warner - <http://egd.sourceforge.net>

the instance of msrl.exe that the malware created previously in C:\Windows\system32\mfm. My findings were as follows:-

I saw DNS requests coming from the infected machine, confirming my TDImon findings. The infected machine was trying to resolve a host called **collective7.zxy0.com** :-

I also saw lots of network activity taking place between UDP port 137 on the infected machine and UDP port 137 on the broadcast ip address (192.168.46.255) and also from UDP 138 on the infected machine to the broadcast address. I understand that UDP port 138 is sometimes used in Netbios exploits but UDP ports 137, 138 and 139 are used by Windows to broadcast information relating to shares. I decided to concentrate on the hostname that the malware is trying to resolve.

My next step was to mould my environment by allowing the malware to resolve the hostname collective7.zxy0.com. I added an entry to the hosts file on my Windows X P virtual machine (C:\Windows\system32\drivers\etc\hosts) to link collective7.zxy0.com with my Linux virtual machine (192.168.46.129). Then I ran the sniffer again.

Now that the malware was able to resolve collective7.zxy0.com, some new network activity began. First of all the malware tried to connect to TCP port **6667** on my Linux virtual machine. However, each time the malware sent a “Synchronize” packet to port 6667, it received an “Acknowledge, Reset”. The malware also tried but failed to connect to TCP ports **9999** and **8080** on the Linux virtual machine. It also received “Resets” for these connection attempts.

Msrl.exe was trying to connect to TCP port 6667 on collective7.zxy0.com which I had resolved to point to my Linux virtual machine. TCP port 6667 is typically associated with IRC servers. So again I moulded my environment by setting up an irc server (ircd) to listen on TCP port 6667 on my Linux virtual machine. I ran Snort again to capture any changes in the malware's behaviour.

This time the malware's connection attempt to TCP port 6667 was successful. After the completion of the three-way handshake, msrl.exe sent the following packet to the irc server:-

```
11/15-01:37:40.808413 192.168.46.128:1092 -> 192.168.46.129:6667
TCP TTL:128 TOS:0x0 ID:294 IpLen:20 DgmLen:131 DF
***AP*** Seq: 0x7ED8C896 Ack: 0xB600931C Win: 0xFAF0 TcpLen: 20
55 53 45 52 20 75 4D 44 57 49 55 57 54 50 58 20 USER uMDWIUWTPX

55 58 50 68 78 58 6B 71 64 7A 0A UXPhxXkqdz.
```

Two keywords stood out in the ascii text – USER and NICK. This is the standard way of logging on to an irc server. The malware (I may refer to the malware as a bot from now on as that is the name given to malware that uses irc.) has provided an obfuscated string of characters for its real name and another obfuscated string for its nickname. Later monitoring showed that these strings change each time the bot connects to the irc server so they must be randomly generated somehow . This goes against my assumptions concerning calls to “dev/random” not working. Maybe the malware has access to another random number generator.

The irc server replied to the above packet with the following packet: -

```
11/15-01:37:40.809603 192.168.46.129:6667 -> 192.168.46.128:1092
TCP TTL:64 TOS:0x0 ID:46074 IpLen:20 DgmLen:86 DF
***AP*** Seq: 0xB600931C Ack: 0x7ED8C8F1 Win: 0x16D0 TcpLen: 20

20 4C 6F 6F 6B 69 6E 67 20 75 70 20 79 6F 75 72 Looking up your
20 68 6F 73 74 6E 61 6D 65 2E 2E 2E 0D 0A hostname....
```

In order to identify the host, a connection was then made from TCP port 1027 on the machine that the irc server is on to TCP port 113 on the infected machine. This was the ident request that I had foreseen. The packet contained the string “1092, 6667” which as you can see from the screenshot above are the ports being used for the irc connection on the respective machines. In reply, the windows virtual machine sent the string “1092, 6667: USERID: UNIX: BwMsQZBNF. Again the text was obscured but the irc server was satisfied, confirming with another packet that it had received the ident response. Eventually, the irc server sent a long welcome message to the infected machine, starting with the following :-

```

11/15-01:38:08.552099 192.168.46.129:6667 -> 192.168.46.128:1092

2B 42 77 4D 73 51 5A 42 4E 46 40 31 39 32 2E 31 +BwMsQZBNF@192.1
36 38 2E 34 36 2E 31 32 38 20 0D 0A 68.46.128 ..

```

The string, “RUXPhxXkq” which was the value of NICK in a previous packet appears many times in the welcome message . In the last part of the welcome message we see the string

“RUXPhxXkq=+BwMsQZBNF@192.168.46.128 ”

The irc server is associating the nickname with the USERID that it received in the ident request earlier. This is standard irc behaviour.

The next packet showed the bot joining a channel called **#mils** on the irc server (JOIN #mils :).

```
11/15-01:38:12.919763 192.168.46.128:1092 -> 192.168.46.129:6667
TCP TTL:128 TOS:0x0 ID:305 IpLen:20 DgmLen:53 DF
***AP*** Seq: 0x7ED8C904 Ack: 0xB60099A0 Win: 0xFAA4 TcpLen: 20
4A 4F 49 4E 20 23 6D 69 6C 73 20 3A 0A JOIN #mils :.
```

Unlike for the values for NICK, USER and USERID , #mils stayed the same each time the bot connected to the irc server . The stop at the end of the packet means 'new line'.

The malware then checked the mode of the channel and the nicknames of those currently present on the channel (MODE #mils.WHO #mils.) :-

```
11/16-00:24:11.546273 192.168.46.128:1057 -> 192.168.46.129:6667
TCP TTL:128 TOS:0x0 ID:256 IpLen:20 DgmLen:61 DF
***AP*** Seq: 0x1A9C622 Ack: 0xDC78FA45 Win: 0xF9CE TcpLen: 20
4D 4F 44 45 20 23 6D 69 6C 73 0A 57 48 4F 20 23 MODE #mils.WHO #
6D 69 6C 73 0A mils.
```

Maybe it was storing these details for the author to pick up at a later date. Or maybe it was comparing the results of these commands to predetermined criteria. It may on the other hand, be looking for a particular nickname, maybe that of the author. If so, it is possible that the nickname of the author is hard -coded into the bot's source code. The same goes for the mode of the channel. Perhaps the Trojan requires the channel to be in a particular mode for some reason. I investigate this further in code analysis.

The irc server responded to these three commands with details of the malware user only as there was no body else connected to the channel .

I assumed that the bot was connecting to the irc channel in order to receive instructions from its author. So I connected to the channel myself to see if I could communicate with the malware and therefore learn more about it. I started an irc client on the Linux virtual machine and logged in. At the prompt I typed “/JOIN #mils” to join the channel. I also tried typing “/JOIN #mils :”. I thought that the bot could be using the colon character as a key for the channel (see Snort log screenshots above).

When I joined the #mils channel (without a key) , the snort log showed the irc server sending a notification of my appearance on the channel to the malware specimen on the infected machine. This is standard behaviour for irc servers. However, it may be worth intercepting this behaviour during code analysis to see if the malware does a text comparison between the name of the new channel member and the name of the author. This is something I could return to in my code analysis later:-

```
11/16-00:25:18.236226 192.168.46.129:6667 -> 192.168.46.128:1057

73 0D 0A
S..
```

I tried out a few irc commands to see if I could get a response from the malware. When I entered the command **/NAMES**, I found that someone called **@sYAyBLAoY** was also logged on to the channel. The @ sign usually means that a user has operator status on an irc channel. **/WHOIS sYAyBLAoY** got the following response:-

is DIQQNFtWitA@192.168.46.128 (QaRdoJNJHZkdNLJkwR) on channels: @#mils on irc server localhost.localdomain (IRC Server) sYAyBLAoY has been idle 30 mins

It is obvious that this user is the bot as the ip address 192.168.46.128 is that of my infected virtual machine . In this case the USERID the malware is using is DIQQNFtWitA. It has been waiting for 30mins. Perhaps it is waiting for a command . The Snort logs showed some periodic “Ping-Pong” activity occurring over the irc connection which can be attributed to the malware trying to keep the irc client alive , again showing that it is waiting for something .

I tried a few other commands without much success . It was time to unpack the malware specimen and run Bintext on the unpacked version . Maybe the Bintext output would contain a list of special commands for communicating with the malware on the irc channel.

When I ran Bintext on msrl.exe at the start of the analysis, one of the strings found was “.aspack” which indicated that the malware was packed with popular packer ASPack. To save time in unpacking the executable I downloaded ASPackDie² from the Internet. I pointed ASPackDie to a copy of msrl.exe on my desktop and it unpacked the malware to a file called “unpacked.exe”, also on my desktop. The first thing I did was to run Bintext on it. A complete list of the embedded strings produced by Bintext can be found in Appendix B.

I scoured the list for command-like strings that I could use to try to communicate with the bot on the irc channel. There were a group of strings beginning with “?” which looked like commands such as “?login”, “?status”, “?kill” .

Returning to the IRC session, I tried out some of the commands beginning with “?” on the #mils channel. However, even though the malware instance was also present on the channel, none of the commands had any affect whatsoever. I tried typing commands with parameters such as ‘?login wrongpassword’ to see if I would get an error response from the Trojan but it still didn’t react. I used Snort to see if any network activity occurred when I entered various commands but all I saw was the trojan sending an Ack packet back to the irc server, acknowledging the command but not doing anything with it.

² ASPackDie v1.4.1 downloaded from <http://mitglied.lycos.de/yoda2k/proggies.htm>

Having failed to communicate with the bot on the irc server, I decided instead to move on to analysing the behaviour of the malware regarding its connection attempts to TCP ports 9999 and 8080. The malware tried to connect to these ports after it was able to connect to what it thought was the collective7.zxy0.com host . I wasn't sure what services the malware was looking for on these ports so I ran NetCat as a listener on each port in turn, starting with TCP port 9999. As an aside, it is worth mentioning that if the malware managed to connect to port 6667 on the collective7.zxy0.com host then it no longer attempted to connect to TCP ports 9999 and 8080.

First of all I shut down the irc server and client that I had started on my Linux virtual machine. Then I set NetCat to listen on TCP port 9999 as follows: -

```
[root@localhost root]# nc -l -p 9999 > /tmp/nc9999.log
[root@localhost root]# more /tmp/nc9999.log
USER ASisT localhost 0 :sGVRTREkqgAqnYDoFMOGJrmOcKBecWtrgwUDXJyJxLzF
NICK TyJdfPQqpN
[root@localhost root]# _
```

Netcat's output showed the data that was sent to port 9999 by the malware. It looks very much like another attempt to log on to an irc server. The USE R and NICK keywords associated with irc connections are there but again their values look as if they are encrypted /random. Later tests showed that the values for USER and NICK changed every time. Maybe in the real world, there is an irc server listening on TCP port 9999 on the collective7.zxy0.com host. I don't have an irc server which listens on this port so I moved on to examine TCP port 8080 connection attempts in the same way.

```
[root@localhost root]# nc -l -p 8080 > /tmp/nc8080.log
[root@localhost root]# more /tmp/nc8080.log
USER cmKsnQSA0m localhost 0 :mgvRPeWrGiahjGPxavdERoNwFWmhPn
NICK BoDsMRNPshJg
[root@localhost root]# _
```

The results are the same as those for port 9999. I will assume that an irc server has been configured to listen on these ports on the collective7.zxy0.com.host as well as on TCP port 6667.

There is one more thing for me to look at in my behavioural analysis. One of the first things I found out about the Trojan was that it was listening on TCP ports 113 and 2200. I established that port 113 was being used to listen for Ident requests and made the assumption that TCP port 2200 was just a simple back door. I tried telnetting to TCP port 2200 on the infected machine from my Lin ux virtual machine and was presented with the following window: -

```
[root@localhost root]# telnet
telnet> open 192.168.46.128 2200
Trying 192.168.46.128...
Connected to 192.168.46.128.
Escape character is '^]'.
#: _
```

I tried typing some simple commands but nothing worked. It is possible that this backdoor was added by the author as an afterthought and maybe even to leave a door open for other hackers to exploit.

Code Analysis

Having taken my behavioural analysis as far as I could, it was time to find out more using code analysis. I had already performed some very basic code analysis by a) running Bintext on the packed executable, b) unpacking the executable with ASPackDie and c) running Bintext on the unpacked executable. The strings that I obtained by running Bintext on the unpacked executable helped me to speculate as to what the Trojan was doing and allowed me to try out some commands on the irc channel. The full list of strings found by Bintext can be found in the Appendix B. Throughout both my behavioural and code analysis I constantly referred back to the strings that were found in the unpacked executable for ideas and clues. At the end of my code analysis I speculate on further functionality of the malware using the embedded strings as a guide.

My behavioural analysis ended at four brick walls which I list here:-

1. The Trojan connected to my irc server on port 6667 on host collective7.zxy0.com and seemed to be waiting for a command. However, I couldn't get it to respond to anything. I hoped to be able to establish with code analysis whether or not:
 - a. The trojan would accept commands from anybody as long as the command was entered correctly
 - b. it required certain criteria to be met in order to be able to respond to commands e.g. the MODE of the channel needed to be set to something special and/or a particular user had to be present on the channel, i.e. the author.
2. The Trojan was listening on TCP port 2200 on the infected machine but again wouldn't respond to any commands I issued to this port via a telnet session from my Linux virtual machine. Maybe my code analysis would give me an idea as to what the Trojan is expecting to receive on this port.
3. If the Trojan wasn't able to connect to port 6667 on collective7.zxy0.com it tried to connect to TCP ports 9999 and 8080. I put listeners on these ports on my Linux virtual machine and recorded the Trojan connecting to them. The Trojan seemed to be expecting irc servers to be listening on these ports too. It authenticated to them in exactly the same way as it did with my irc server on port 6667. I could configure Honeyd to emulate an irc server listening on these ports but there is little point in doing this until I can get over my first brick wall.
4. There is also the fact that most of the communications coming from the Trojan seem to be encrypted. As if that wasn't enough the communication strings also seem to be randomised. Many of the strings found by Bintext support this. A full list of relevant strings can be found in Appendix C.

The main focus of my code analysis is therefore working out how to communicate with the Trojan.

The tools that I used were:

Bintext – to find embedded strings

IDAPro – to disassemble executable into assembly code

OllyDebug – to step through disassembled code

PEInfo – to view the malware's imported files and functions and also its structure ,

Snort – to sniff packets off network

I thought that if I could locate one of the hard-coded irc-like commands in the code of the malware then I might be able to see how the malware expected to receive them , e.g. the format of the commands and any hard coded parameters such as passwords.

Having already unpacked the malware specimen to the desktop, the next time I double-clicked on the unpacked version, it overwrote the packed version of msrl.exe in the C:\Windows\System32\mfm folder and deleted itself from the desktop. So, I loaded the unpacked C:\Windows\system32\mfm\msrl.exe into IDA Pro to disassemble it and began my analysis by searching (Alt+T) the assembly code for the '?login' string .

However, IDAPro couldn't find "?login". I tried searching for other irc-like command strings e.g. '?status' and '?kill' but IDAPro couldn't find those either. This didn't make sense. I checked out the list of Strings that IDAPro automatically generated on loading msrl.exe but the irc-like command-strings weren't there either. Bintext said that the string was supposed to be at memory location 0040935D but in IDAPro the addresses jumped from 00409345 to 004094B1. However, starting from 00409345 were a large group of dd (double word) declarations in hexadecimal.

.text:00409345	dd 69733Fh, 6C73733Fh, 6C633F00h, 656E6F
.text:00409345	dd 676F6C3Fh, 3F006E69h, 69747075h, 3F00
.text:00409345	dd 3F00746Fh, 74617473h, 3F007375h, 706D
.text:00409345	dd 3F006B63h, 6F686365h, 75683F00h, 3F00
.text:00409345	dd 6F6A3F00h, 3F006E69h, 3F00706Fh, 706F
.text:00409345	dd 3F006B63h, 74726170h, 75643F00h, 3F00
.text:00409345	dd 6569643Fh, 646D3F00h, 3F007035h, 6565
.text:00409345	dd 753F0077h, 74616470h, 683F0065h, 6E74
.text:00409345	dd 6669663Fh, 66213F00h, 3F006669h, 6C65

I thought that maybe the hexadecimal equivalent of "?login" could be somewhere amongst the declarations . Maybe the declarations themselves were referenced in the code rather than their memory location. On converting a few of the declarations to ascii I found that they were indeed a list of commands but it would take too long to convert it all in order to find my ?login command. .

I switched to Hex View in IDAPro to see if I could shed any light on which of the dd declarations contained the "?login" command (see screen shot below) .

.text:00409340	5B	5E	5F	5D	C3	3F	73	69-00	3F	73	73	6C	00	3F	63	"[^_]+?si.?ssl.?c"
.text:00409350	6C	6F	6E	65	00	3F	63	6C-6F	6E	65	73	00	3F	6C	6F	"!one.?clones.?lo"
.text:00409360	67	69	6E	00	3F	75	70	74-69	6D	65	00	3F	72	65	62	"gin.?uptime.?reb"
.text:00409370	6F	6F	74	00	3F	73	74	61-74	75	73	00	3F	6A	75	6D	"oot.?status.?jum"
.text:00409380	70	00	3F	6E	69	63	6B	00-3F	65	63	68	6F	00	3F	68	"p.?nick.?echo.?h"

On the right hand side are the ascii strings including “?login” and in the middle is the equivalent hexadecimal. The hexadecimal equivalent of “?login” is “3F 6C 6F 67 69 6E” but it is split over two memory addresses, 00409350 and 00409360. Therefore I would expect one of the dd declarations to contain “3F 6 C 6F” and another to contain “67 68 6E”.

3F	6C	6F		67	69	6E
?	L	o		G	I	N

However, in double word declarations the hexadecimal pairs are reversed as follows:-.

6F	6C	3F		6E	69	67
O	L	?		N	i	G

Referring back to the dd declarations, one of the declarations contains the first three pairs:-

676F6C3Fh with an extra pair, 67 (“g”) at the start and the next dd declaration, 3F006E69h contains the pairs 6E and 69 with two extra pairs at the start. If I convert these declarations back into hex I get “?I ogin.?”. The final character is part of the next command.

I searched IDAPro to see if it could find any references to the first dd declaration 676F6C3Fh. No references were found for either of the dd declarations. A quick browse through some of the code in IDAPro showed that dd declarations are often referenced using ‘dword_memory location of declaration is at’. I tried searching for dword_409350 and also for dword_409345 but IDAPro found nothing.

I was unsuccessful in using IDAPro to locate calls to the “?login” command.

During my behavioural analysis I suggested that the Trojan may be testing to see if certain criteria are met when it issues the MODE #mils and WHO #mils commands after joining the channel. Related strings found by Bintext were “ WHO %s” at address 00403778 , “%s logged in” at address 00405B88, “ MODE %s -o+b %s *@%s” at address 00404711, “ MODE %s -bo %s %s” at address 004047E7, “ MODE %s %s” at address 0040505A, “ mode %s +o %s ” at address 004055A3 and at address 004134B0, “ mode %s +b %s %s ” at address 004055B8 and “_setmode” at address 0051BCFA.

The “MODE” command is referred to several times in the code and in particular with the attributes ‘o’ and ‘b’ which stand for ‘operator status’ and ‘ban’ respectively in irc - speak. One of the strings above, “ mode %s +o %s ”, could be used to give ‘operator status’ to someone. An operator has special privileges on an irc channel. You can

only become an operator either by being the first person to join a channel or by being given operator status by an other operator. Perhaps the Trojan gives operator status to its master when the master joins. Or maybe it gives operator status to other instances of the malware that join the channel. I should let the malware join the #mils channel before I do in further analysis to make sure that it gets operator status.

Why would the Trojan want to ban or remove a ban from another channel member? Maybe this will become clear on analysing the code.

Starting with the “WHO %s” string, Bintext said that it is located at 00403778.

However, in IDAPro the addresses jump ahead from 00403775 to 00403781. In between were three dd (double word) declarations and a cross reference to a subroutine (sub_403783+4C).

```
.text:00403774 ; -----  
.text:00403775 dword_403775 dd 25207325h, 48570A73h, 7325204Fh  
.text:00403775 ; DATA XREF: sub_403783+4C↓  
.text:00403781 ; -----
```

This is the same issue that I came across previously when searching for the “?login” string.

The three dd declarations were the hexadecimal values 25207325h, 48570A73h and 7325204Fh.

Hex	25	20	73	25		48	57	0A	73		73	25	20	4F
Asc	%	Space	S	%		H	W	Line Feed	S		S	%	Space	O

I changed the order of the hex values so that the first word of each 4-word value is at the end of the 4-word value and the last word is at the start of the 4-word value.

Hex	25	73	20	25		73	0A	57	48		47	20	25	73
Asc	%	S	Space	%		s	Line Feed	W	H		O	Space	%	s

The “WHO %s” string is there. I have highlighted it in bold.

I examined the cross-referenced subroutine sub_403783+4C mentioned above and found a reference to the memory location of the WHO %s string, dword_403775 (00403775 is the start of the dd declarations) :-

```
... .text:004037C8        duu      edx, 4000h
*.text:004037C8    push    eax
*.text:004037C9    push    eax
*.text:004037CA    push    offset aMode      ; "MODE"
*.text:004037CF    push    offset dword_403775
*.text:004037D4    push    [ebp+arg_4]
*.text:004037D7    push    0
*.text:004037D9    push    0
*.text:004037DB    call    sub_404481
*.text:004037E0    add     esp, 14h
```

Not surprisingly, the string “MODE” is in the instruction above it. Looking at the above code, it seems that both “MODE”, “WHO %s” and a few other values including the value in the EAX register and the contents of what’s at memory address EBP + FF (arg_4) are passed in to a subroutine at memory location 404481 (call sub_404481) . I examined subroutine 404481 in ADIPro but could not really tell what was happening . I then viewed the code with a debugger, Ollydbg in the hope of seeing some hard - coded ascii values which the trojan may have been using for string comparisons . I opened msrl1.exe in OllyDbg and set breakpoints (F2) at the following positions: - 004037DB (the call to the subroutine), 004037E0 (the instruction after the subroutine) and 00404481 (the first instruction of the subroutine). Then I ran the malware (F9). The malware stopped at the first breakpoint. The contents of memory address EBP + arg_4 turned out to be the user id!nick@host combo for the Trojan that had joined the irc channel with a colon in front and the string “JOIN #mils” at the end like this: -

":DwCyuDrDY!cZKN@192.168.46.128 JOIN :#mils"

I pressed F7 to step into the subroutine. I stepped through each line of the subroutine (F8). The code calls subroutine 411D10 and continues. Then at instruction 411D3B the code jumps to the address that is in the EAX register, which is 404491. Then at 4044C1 the code jumps a few instructions to address 4044DC (referred to as msrl1.004044DC which means that this code is part of the malware’s code rather than part of a packaged dll file or some other program). At instruction 4044E2, the magic address BAADFOOD is initialised with 0. The next jump is to 00404565. At address 404578, “USERHOST nQwRsDAIE” is printed to the screen of the irc server using the function vsnprintf from the msvcrt.dll. A comparison is made at address 4045A4 and the next line of code jumps a few lines to 4045CA if the two values that were compared were equal (JE SHORT msrl1.004045CA). Each time I run the malware, this jump is never taken because the comparison is successful. However, I can see in Ollydbg that the lines of code being jumped are printing something to the screen:

```

004045A1: 83C4 10 ADD ESP,10
004045A4: 83BD E4FFFFFF CMP DWORD PTR SS:[EBP-101C],0
004045A8: v74 1D JE SHORT msrl1.004045CA
004045AD: 83EC 0C SUB ESP,0C
004045B0: 53 PUSH EBX
004045B1: FF75 0C PUSH DWORD PTR SS:[EBP+C]
004045B4: FFBS E4FFFFFF PUSH DWORD PTR SS:[EBP-101C]
004045BA: 68 72444000 PUSH msrl1.00404472
004045BF: 50 PUSH EAX
004045C0: E8 0BDC0000 CALL <JMP.&msvcrt.sprintf>
004045C5: 83C4 20 ADD ESP,20
004045C8: vEB 1A JMP SHORT msrl1.004045E4
004045CA: > 83EC 08 SUB ESP,8

```

<%s>
 <%s>
 <%s>
 format = "%s %s :%s"
 s
sprintf

I used OllyDbg to replace the compare function at 004045A4 with a NOP instruction to stop the jump from taking place . This is called ‘patching’ and is done by selecting the line of code and then pressing the space bar. Enter ‘NOP’ in the box, hit Assemble and you will get the following. The change is only made to memory, not to disk.

```

00404594 | . E8 B7000000 C9HLL <JMP.&msvort.malloc>
00404599 | . 8B95 E0FFFFFF MOV EDX,DWORD PTR SS:[EBP-1020]
0040459F | . 8902 MOU DWORD PTR DS:[EDX],EAX
004045A1 | . 83C4 10 ADD ESP,10
004045A4 | . 90 NOP
004045A5 | . 90 NOP
004045A6 | . 90 NOP
004045A7 | . 90 NOP
004045A8 | . 90 NOP
004045A9 | . 90 NOP
004045AA | . 90 NOP
004045AB | . 74 1D JE SHORT msrll.004045CA
004045AD | . 83EC 0C SUB ESP,0C
004045B0 | . 53 PUSH EBX
004045B1 | . FF75 0C PUSH DWORD PTR SS:[EBP+C]
004045B4 | . FFBS E4EFFFFF PUSH DWORD PTR SS:[EBP-101C]
004045B8 | . 68 72444000 PUSH msrll.00404472
004045BF | . 50 PUSH EAX
004045C0 | . E8 0BD00000 CALL <JMP.&msvort.sprintf>
004045C5 | . 83C4 20 ADD ESP,20

```

malloc

<%s>
 <%s>
 <%s>
 format = "%s %s :%s"
 s
 sprintf

Actually, the code turned out to be much less interesting than I thought. The malware was just preparing the string USERHOST userid for printing to the irc server. Moving on, the next thing of any significance that I saw was at instruction 00403845. The userid part of the above string ("DwCyuDrDY") was being copied into the address 003D7300, the user!nick@host part of the string was being copied into 003D736D, the ip address (192.168.46.128) was being copied into 3D7C27 and "#mils" was being copied into 3D78A8. However, later debugs showed that these memory addresses changed with every run of the malware.

I gathered from the code that I had been following so far in OllyDbg that the malware was simply preparing strings about itself for introducing itself to the irc server. Nothing very exciting.

The furthest I got in following this path was to see the malware comparing the string "001" with the following strings: "JOIN", "QUIT", "352", "302", "303", "005", "NICK", "PART", "KICK", "353", "MODE", "433" and "324". It seemed to find a match with "324" and exited the loop which was at address 00404233. This is something new. The numbers seem to represent commands. What command could the string "001" represent? Unfortunately, I was unable to establish using code analysis whether the malware was checking to see if certain conditions were met after it joined the channel.

Many of the strings found by Bintext were functions from various dlls that were imported by the malware from the infected system. I used a tool called PEInfo to see which dll files and which functions the malware was importing. Below you can see a list of dll files that the trojan requires under 'Imports' on the left and on the right, a list of functions that the selected dll file contains (I have selected ADVAPI32.dll in this example) :-

Import Name: ADVAPI32.DLL			
Name:	0051C0FC	Characteristics:	0051B0CC
TimeStamp:	00000000	Not bound	
Thunk	Ordinal	Name	
0011B108	481	StartServiceCtrlDispatcherA	
0011B104	475	SetServiceStatus	
0011B100	437	RegisterServiceCtrlHandlerA	
0011B0FC	430	RegSetValueExA	
0011B0F8	388	RegCreateKeyExA	
0011B0F4	384	RegCloseKey	
0011B0F0	356	OpenSCManagerA	
0011B0EC	355	OpenProcessToken	
0011B0E8	276	LookupPrivilegeValueA	
0011B0E4	243	GetUserNameA	
0011B0E0	120	CryptReleaseContext	
0011B0DC	110	CryptGenRandom	
0011B0D8	93	CryptAcquireContextA	
0011B0D4	90	CreateServiceA	
0011B0D0	58	CloseServiceHandle	
0011B0CC	25	AdjustTokenPrivileges	
Import count: 16			

Immediately, I recognised some of the function names from my Bintext output, including CryptGenRandom and CryptAcquireContextA. I believe that the malware has even packaged up at least one whole program with itself. For example, it is unlikely that the malware would be able to find the LibTomCrypt program on an infected computer so it seems to have packaged the whole program up with itself. I went to the features page of LibTomCrypt on the WWW (<http://libtomcrypt.org/features.html>) and practically every string from this page was found by Bintext. What are the bets that the features page is the same as the readme file that comes packaged with LibTomCrypt? It would be nice to be able to eliminate these strings from the Bintext output to make analysis simpler.

Analysis Wrap-up

The capabilities of this specimen of malware are far-reaching. Infection takes place through execution of the specimen on a MS Windows operating system and it runs with the privileges of the logged-in user which is SYSTEM in the case of most home users. On infection it deletes itself from the place it was executed, it adjusts the Registry so that it runs as a process each time the computer is started up and it copies itself along with another file into a folder in the system path. It takes measures to hide itself from the user such as using a fake display name in Services.

The specimen then opens a backdoor on TCP port 2200. Meanwhile it tries to connect to a host called collective7.zxy0.com. If successful it tries to connect to an irc server listening on port 6667 on that host. If it fails then it tries to connect to back-up irc servers listening on ports 9999 and 8080. After connecting to port 6667 the malware joins a channel called #mils and queries the irc server to find out the mode of the channel and the names of other channel members. Then it waits. I believe that it is waiting for commands from its master.

The malware has advanced encryption capabilities, making use of various cryptographic providers and random number generators. The userid and nickname it

provides to the irc server are randomly generated. Also, the malware writes several long encrypted values to the jtram.conf file that it copied into the system path . Many of the embedded strings produced by Bintext look as if they are encrypted as well as function names and file names that indicate that encryption is being used (see Appendix C for encryption/randomisation -related strings).

Even though I failed to get the bot to react to any of my commands, the embedded strings gave many clues as to what an attacker could use it for: -

Strings such as 'jolt', 'syn' and 'smurf' (see Appendix C, Attack-related strings) indicate that the master could command the bot (and perhaps hundreds of other bots at the same time) to launch various DoS attacks the victim machine or on a target other than the victim machine.

Commands such as '?reboot', '?crash' and '?rmdir' show that the bot can be used by an attacker to cause trouble on the infected machine.

A selection of strings beginning with SSL e.g. SSL_connect show that the malware is capable of talking over the WWW . Maybe it connects to a web site or web server to receive instructions from its master or maybe it can download files from a web server. Strings such as "urlopen failed" and "inetopen failed" confirm that the malware can communicate via the WWW.

There are many strings which contain 'dcc' which is a Direct -client-to-client function in IRC (see Appendix C - DCC and IRC Socket related strings). DCC is commonly used to distribute malicious code to unsuspecting users. Perhaps the malware is using it in this way too. It could use DCC to receive updates from its master or to send data to its master.

The malware has all the capabilities needed to be a serious attack tool. It can be modified and improved upon by its attacker , making it more dangerous and versatile. It already has several built -in back-up components such as the connection attempts to ports 9999 and 8080.

The Trojan is very difficult to authenticate to – I assume that a degree of cryptanalysis would be necessary to establish the key required to be able to communicate with the Trojan. That means that it has not been designed for use by anyone who just happens upon it.

Depending on the infection rate, the #mils channel could be a meeting point for thousands of bots identical to this one. The attacker would then have the capability to launch a serious DoS attack on his adversary or on a commercial company or website or on a government website and so on. This kind of malware is being used more and more to conduct crimes of extortion. Basically, a criminal commands his zombies (the thousands of bots that have gathered in his irc channel) to launch a particular denial of service attack (e.g. jolt) against a company and refuses to stop it until a large sum of money is transferred to an off -shore bank account. It is almost impossible to track this type of attack back to its source because the DoS attacks are coming from unsuspecting users' infected machines located all over the world.

The string “% removed” was found by Bintext. This indicates that I may be able to issue a command to the Trojan on the irc channel telling it to remove itself from the machine it has infected. However, as I can’t authenticate to the Trojan, I would take the following three steps to remove it from my system: -

1. Stop the msrl.exe process using Task Manager
2. Open up Services from Control Panel and locate the service called “RII enhanced drive”. Right click on the service and choose properties. Change the Start-up type of the service from “Automatic” to “Disabled”. This is one step towards stopping the malware from starting up automatically next time you start up your computer. However, you also need to reverse the changes that were made by the malware to your registry settings. Locate the following keys in the Registry (use Regedit from a command prompt) and delete the whole of the ‘mfm’ key:-

HKEY_LOCAL_MACHINE \SYSTEM\ControlSet001\Services\mfm
HKEY_LOCAL_MACHINE \SYSTEM\CurrentControlSet\Services\mfm

3. Delete the folder called ‘mfm’ from “C:/Windows/system32/”.

The main piece of advice that I would give to avoid an attack by this specimen would be not to log on to your computer as System Administrator by default. This malware specimen assumes the privileges of the logged in user. Only the users with System privileges are able to make changes to the Registry. Therefore, if you were infected by the Trojan whilst logged in as a standard user, the malware would be unable to make the necessary changes to the Registry. That means that the service (RII Enhanced Drive) that causes the malware to run automatically each time the computer is started up, is never created.

Secondly, monitor your computer’s listening ports . Close any ports that are open and listening unnecessarily. I did not find out exactly what TCP port 2200 is used for in this particular case. However, closing it can only protect you further as this port is not commonly used for anything else.

Appendix C

Encryption/Randomisation -related strings

String	Description
%s <pass><salt>	a salt is usually a couple of random characters that are used by an encryption routine to randomise the output.
/dev/random	“this is a little character device that gives you random numbers when you read it.” Many encryption routines “use this device to seed a secure random number generator” ³ . However, it is not present on MS Operating systems.
DiCHFc2ioiVmb3cb4zZ7zWZH 1oM=	a hard-coded string that looks as if it is encrypted or maybe it is a key used by the encryption routine.
“\$1\$KZLPLKDf\$W8kl8Jr1X8D OHZsmIp9qq0” “\$1\$KZLPLKDf\$55isA1ITvam R7bjAdBziX.”	More hard-coded strings that seem to be encrypted. Interestingly the first part of each string is the same - \$1\$KZLPLKDf\$ - also, the dollar signs seem to split the string up into sections.
./0123456789ABCDEFGHIJKLM NOPQRSTUVWXYZabcdefg hijklmnopqrstuvwxyz	This and similar strings could be used as part of the encryption routine.
sprng, sprng.c	A set of libraries for scalable and portable pseudorandom number generators.
rc6.c	An encryption algorithm
skey, key, desired_keysize	
crypt.c, cipher, hash	
LibTomCrypt 0.83, Endianess: little (32-bit words) Clean stack: disabled Ciphers built-in: Blowfish RC2 RC5 RC6 Serpent Safer+ Safer	A “cryptographic toolkit that provides developers with a vast array of well known published block ciphers, one-way hash functions, chaining modes, pseudo-random number generators, public-key cryptography and a plethora of other routines.” ⁴ I found so many strings relating to this program that I believe that LibTomCrypt is packaged up with the malware.

³ <http://egd.sourceforge.net>, EGD: The Entropy Gathering Daemon by Brian Warner

⁴ <http://libtomcrypt.org/features.html>

<p>Rijndael XTEA Twofish CAST5 Noekeon Hashes built-in: SHA-512 SHA-384 SHA-256 TIGER SHA1 MD5 MD4 MD2</p> <p>Block Chaining Modes: CFB OFB CTR Yarrow SPRNG RC4</p> <p>PK Algs: RSA ECC</p> <p>Compiler: WIN32 platform detected. GCC compiler detected.</p> <p>Various others: BASE64 MPI HMAC</p>	
Microsoft Base Cryptographic Provider v1.0	A Cryptographic Service Provider is an independent software module that performs cryptography algorithms for authentication, encoding and encryption. This one comes with Internet Explorer 3.0 or later.
CryptAcquireContextA CryptGenRandom CryptReleaseContext	These three functions belong to ADVAPI32.dll. This dll name can also be found in the strings.

Attack-related strings

String	Description
jolt2: done,	Jolt is the name of a DoS attack which affects Windows 95 and NT machines. ⁵ "The attack sends very large, fragmented ICMP packets to a target

⁵ <http://www.physnet.uni-hamburg.de/physnet/security/vulnerability/jolt.html>

	machine.” The packets “are fragmented in such a way that the target machine is unable to reassemble them for use.”
smurf done, ?smurf	A Smurf attack is a network level attack against hosts. ⁶ An attacker sends a large amount of ICMP traffic to a broadcast address, spoofing its source address to look like it’s coming from the victim. All the hosts on the network (that receive the ping) respond to the victim, causing a denial of service.
syn: done	A Syn attack is when an attacker sends lots of Synchronization packets to a victim, saturating the network and causing a denial of service.
?reboot, ?rmdir ?mkdir, ?crash ?sklist, ?dccsk ?killsk	A selection of what could be irc commands which look as if they could cause some trouble.

SSL-related strings

String	Description
SSL_get_error SSL_load_error_strings SSL_library_init SSLv3_client_method SSL_set_connect_state SSL_CTX_new SSL_new SSL_set_fd SSL_connect SSL_write SSL_read SSL_shutdown SSL_free SSL_CTX_free	SSL is Secure Sockets Layer. It is used for secure communication via the WWW. Maybe the malware is able to access a web server to receive instructions or maybe download files or updates.

DCC and IRC Socket-related strings

String	Description
“dcc_wait: get of %s from %s timed out” “dcc_wait: closing [%#%u]	DCC is Direct-Client-to-Client. You can send and receive files over IRC with this function. You can also chat directly, privately and securely to

⁶ <http://www.pentics.net/denial-of-service/white-papers/smurf.cgi>

<pre>%s:%u (%s)" "%u Send(s) %u Get(s) (%u transfer(s) total) UP:%ucps DOWN:%ucps Total:%ucps" "send of %s incomplete at %u bytes" "send of %s completed (%u bytes), %u seconds %u cps" "cant open %s (err:%u) pwd:{%s}" "DCC SEND %s %u %u %u" "dcc.pass" ?dccsk DCC ACCEPT %s %s % dcc_resume: cant find port %s dcc.dir %s\%s\%s\% unable to open (%s): %u resuming dcc from %s to %s DCC RESUME %s %s %u</pre>	<p>someone on IRC. It does not use chat channels to transmit information, rather it forms a direct link between two users.</p> <p>The strings found by Bintext indicate the Trojan has the capability to transfer data. There may also be a password involved ("dcc.pass"). Maybe the malware is using port 2200 to receive data from the attacker.</p>
<p>Set an irc sock to preform %s command on</p> <p>Type %csclist to view current sockets, then %cdccsk</p>	

Strings related to attacker updating the malware specimen

String	Description
?insmod ?rmmmod ?lsmmod %s: <mod name> %s: mod list full mod_init mod_free %s: %s loaded (%u) %s: mod already loaded %s: unloading %s %s: %s not found finished %s	The attacker may use these commands to check to see if the malware specimen already has a particular module. The attacker may be able to upload a module if necessary or remove a module.
